Through the years, the series also had its share of add-ons, such as the *Metal Solid: VR Missions* (1999). Rereleases included *Metal Gear Solid: Subsistence* (2005), an iteration of the third canonical game, which includes both original MSX2 *Metal Gear* games, making them available to the North American market. Compilations of the series include the *Metal Gear Solid: HD collection* (2011 and 2012).

The series mainly revolves around the missions of four elite soldiers: Naked Snake (*MGS3*, *MGS: Portable Ops*, *MGS: Peace Walker*, *MGSV: GZ*), who will later become known as Big Boss (the “genetic father” of Solid Snake, Liquid Snake, Solidus Snake, and the Genome soldiers); Venom Snake (*MGSV: TPP*); Solid Snake (*Metal Gear*, *Metal Gear 2*, *MGS*, *MSG2's Tanker Episode*, *MGS4*);

and Raiden (*MGS2*, *MGR*). Each mission ultimately involves finding and neutralizing the many iterations of the Metal Gear, a bipedal (Metal Gear Zeke, D, TX-55, Rex, Rey, and Gekkkō) or submersible (Arsenal Gear) tank with nuclear missile launching capabilities.

According to the *Metal Gear Solid 4 Database*, although the games take place between 1964 (*MGS3*) and 2014 (*MGS4*), the story's timeline begins in early American history, when the Patriots created the Sons of Liberty, a name that will later be used by Solidus Snake's terrorist group in the events of *MGS2* (this still holds true as of 2019, as the *MGSV* opuses take place between 1974 and 1984, and the 2018 events of *MGR: Revengeance* are not considered canon). The series' fictional events and characters' backstories are often connected with actual historical events, and the series also tends to blend real scientific facts and military technology with their fictional equivalents. For example, although the gamer might need to administrate diazepam, a real benzodiazepine-derived drug used for treating anxiety, insomnia, seizures, and muscle spasms, to stabilize the aim of the player character, the protagonist's stamina, strength, and reflexes are also enhanced by injected (and fictional) nanomachines that can supply adrenaline, nutrients, and sugar or restrict the host's actions. The same goes for the military and scientific organizations—such as the CIA, DARPA (real), and FOX HOUND (fictional)—involved in the series' conflicts. This mixture of facts and (science) fiction is one of the defining traits of the *Metal Gear* saga.

Initially designed to be an action wargame, the technical limitations of the MSX2 forced Kojima to reconsider

his overall gameplay stance. As he explained in a *Gamers Today* interview, “Creating a war game for MSX was a little difficult because of the limitation on the sprites. When you get four enemies or even four bullets on the screen at once, the screen starts blinking and it just doesn't work” (Kent 1998). Therefore, the game designer decided to take another approach. Instead of fighting all the soldiers, the player character would have to sneak past them and avoid being spotted. To circumvent opposition, the games have a large inventory of infiltration tools, the most famous being the cardboard box, as well as many weapons that often serve more than offensive purposes. Although most of the gameplay mechanics were enhanced or refined through the course of the series, many were already present in the 1987 game. As a result, the original *Metal Gear* is often identified as the game that introduced the stealth genre, whereas *Metal Gear Solid*, the first title of the series published worldwide, is widely recognized as the game that made the genre popular.

The *Metal Gear* series demonstrates Hideo Kojima's interest in filmmaking through movie references and the series' general aesthetic. Each game begins with an opening title with the names of the voice actors and relies heavily on cutscenes. During gameplay, the games rely on an overhead or over-the-shoulder third-person point of view that, at certain points, changes to prescribed fixed camera shots, adding to the cinematic feel of the games. Most games of the *Metal Gear Solid* series also allow the player to switch to a first-person point of view. This perspective is often treated as if the player character had a camera

instead of eyes, as seen in *MGS2* when droplets of rain accumulate on the screen. This tends to reinforce the feeling that the gamer's journey is mediated through a filmic apparatus.

The series is also renowned for its high degree of videoludic self-consciousness. At many points during a gameplay session, the gamer is reminded of his or her role within the simulation. Although this auto-reflexivity is constantly and subtly present under different forms within the games, it occasionally peaks by having the characters refer directly to the interface and game hardware. For example, in *Metal Gear Solid*, during the battle against Psycho Mantis, Roy Campbell—Solid Snake's commander—asks the gamer to plug the game controller in the second port of the console to prevent the psychic Fox Hound member from using his telepathic powers.

Although the series is widely acknowledged for its original and immersive gameplay, Hideo Kojima's vision as a video game author and the game's resulting intricate narrative—mostly delivered through lengthy noninteractive sequences (some can run up to an hour)—has received its just share of praise and criticism from the gaming community and academic circles. For Steven Poole, “the multiple twist and turns of the thriller plot are highly enjoyable, dropping little hints as to the true nature of your mission and the organisation you work for, keeping you guessing as to how it will all turn out” (Poole 2000, 110). Whereas for Grant Tavinor, “the tone of the games is widely erratic, with vulgar jokes placed alongside very stylish sequences intended to convey seriousness” (Tavinor 2009, 113). The poor taste of some of these creative choices eventually led to

controversy. For instance, the rather revealing outfit of *MGSV*'s character Quiet—including the game's rather unconvincing explanation that she can only breathe through her skin—as well as the mishandling of sensitive themes such as sexual violence in *MGSV: GZ* led to accusations of sexism and misogyny from both critics and the gaming community. Such chauvinistic takes on the representation of women, which can be traced back to a *Metal Gear Solid*'s Easter egg that allowed the players to catch Meryl Silverburgh in her underwear, providing that they follow her into a women's bathroom quickly enough, are indeed questionable and detract from the otherwise profound antimilitary, antinuclear, and technoskeptical messages as well as the identity-oriented and relationship-oriented themes of the games.

As for the excessively long cutscenes, in an interview given to Adam Doree (for *Kikizo*) in 2008, Kojima expressed doubts about the effectiveness of a certain type of interactive storyline in which the gamer is free to select what he wants to see. While confessing that he chooses “the easy way” when using cutscenes to carry the narrative of the games, he also stresses that doing otherwise might not get the gamer as emotionally involved. Therefore, while the sometimes unbalanced ratio between gameplay sequences and cutscenes, combined with the occasional crude and misplaced humor, might be polemical, they remain a truthful reflection of Kojima's vision of storytelling and true to his style as a game designer and video game author (Stanton 2015).

Metalepsis

Metalepsis roughly translates to "frame breaking" and refers to moments within a story in which various levels of narration become muddled: narrators may comment on the fact that they are relating a story, and authors may interject themselves into the narration to draw attention to the fact that the story at hand is their invention. Originating in classical Greek (legal) rhetoric, the term was introduced to literary studies by the French narratologist Gérard Genette, who defines it as "any intrusion by the extradiegetic narrator or narratee into the diegetic universe (or by diegetic characters into a metadiegetic universe, etc.), or the inverse" (1980 234–235). Narratologists have since expanded Genette's definition to further distinguish, among others, between rhetorical, or minimalist, metalepsis, in

which narrative and narrated world remain separate, and ontological metalepsis, in which entities from either level of narration interact directly (Kukkonen and Klimek 2011; Pier 2013; and Ryan 2004). While it remains an understudied concept in video game studies (Giaponne 2015; Harpold 2007; Schlarb 2019), media studies scholars have proposed considering metalepsis as the very framework for understanding player interaction with the diegetic world of narrative-driven games (Neitzel 2007).

Scholars in media studies, culture studies, and aesthetics continue to debate the term's exact scope and efficacy. Technically, metalepsis designates a referential shift. Like its figurative brethren, *metaphor* and *metonymy*, metalepsis belongs to a group of phenomena that are syntactically and etymologically ambivalent. Genette uses the term inconsistently in his study, but others have noted it to constitute a "contamination" and a "violation of sematic thresholds" (Pier 2013). Despite these attributes, however, metalepsis does not in all cases disrupt narrative illusion and therefore is not inherently transgressive (Klimek 2010). From this vantage point, metalepsis, together with other disruptive aesthetic phenomena (e.g., glitches), emblemizes the fundamental instability of all representation.

Some consider metalepsis an emergent phenomenon that forms part of a larger (postmodern) trend according to which media become increasingly self-referential, self-reflexive, or autotelic (cf. Nöth 2007). This diagnosis has generated controversy regarding the status of semiotic referentiality: while some celebrate an increase in self-referentiality as a sign of "increasing critical consciousness" and

thus of a medium's aesthetic maturation, others are weary of this trend because it implies that representation can work without recourse to any external (material) referent. The role of video games in this debate remains contested, even though some have claimed that games are the medium par excellence for demonstrating the referentially hermetic nature of all representation (Nöth 2007, 7).

The act of “breaking the fourth wall” is also prominent in performative media such as theater and film. For instance, Berthold Brecht's epic theatre attempts to cultivate political awareness in its audience by trying to prevent cathartic identification with the *dramatis personae*. Actors address the audience directly and refer to their characters as roles they play so as to disrupt the illusion. Rhetorical metalepsis has also become common practice in comic books (e.g., the *Maus* and *Deadpool* series) as well as film and television series (cf. Feyersinger 2010; e.g., *House of Cards*). Across all media, the efficacy and potential radicalness of metalepsis depends on both audience expectations and media affordances (Kukkonen and Klimek 2011).

Video games display the full spectrum of metaleptic meaning, ranging from mundanely diegetic to subversive. For starters, any pause or options screen may be considered metaleptic. In the same vein, command line, text-based adventures such as *Zork* (cf. Neitzel 2007) address players directly to prompt input. In the last decade, major publishers' attempts at expanding and diversifying audiences in terms of age and gender demographics have fostered more complex narratives with multiple frames and mature themes. Most narrative-driven games contain metaleptic elements, such

as transmedial storytelling (*Quantum Break* [2016]), multiple narrative perspectives (*Beyond Two Souls* [2013] and *Detroit: Become Human* [2018]), and interactive storytelling (Telltale Game's *Walking Dead* series [2012–18]).

Several games include metaleptic moments that are more in line with Genette's original definition and feature various degrees of subversiveness (cf. Schlarb 2019). For instance, the hack-and-slash adventure game *X-Men* (1993), for the SEGA Genesis, asks players to “reset the computer” in one of its later levels. Players are expected to lightly tap the console's reset button rather than flick any virtual switch in the game world. The game did not have a “save file” feature; therefore, players were risking their progress if they held the button down too long. In *Metal Gear Solid* (1998), a character with telekinetic and telepathic abilities activates the controller's vibration feature and reads the content of memory cards, depending on the player's dialogue choices. *Batman: Arkham Asylum* (2009) includes a sequence in which players see glitches (visual and audio artifacts) and are made to think that their consoles have broken down, just as Batman, the protagonist, suffers the effects of a fear-inducing toxin (see also Glitches). Meanwhile, the eponymous protagonist of *Deadpool* (2015) argues on the phone with the game's director over budget and level design.

Metagames, a genre that has garnered commercial and critical acclaim in the past decade, is arguably structured almost exclusively around the principle of metalepsis. *Pony Island* (2016) employs at least four discernible levels of narrative framing: players interact with a cursed virtual arcade cabinet by (1)

playing through the cabinet's mundane jump-and-run game, (2) hacking and manipulating its core code, and (3) text messaging with several entities (a ghost and Satan) "haunting" the cabinet. After completing the game, (4) the same ghost prompts players to erase the game from their computers to set it free. The first-person-perspective puzzle game *The Stanley Parable* (2011) features a narrator who comments in real time on the protagonist's (and thus the player's) actions and routinely intervenes in the game's plot by adding plot devices, such as a time bomb, and by looping and restarting the story.

Overtly disruptive forms of metalepsis occur in the context of piracy and cheat prevention on the side of game publishers. Pirated copies of *Grand Theft Auto IV* (2008) feature a permanently shaking camera that makes navigating the game world virtually impossible. *Alan Wake* (2010) displays the eponymous protagonist with an eye patch, a stereotypical cultural marker for pirates. Online multiplayer games such as *World of Warcraft* (*WoW*) have even created so-called prison servers that segregate players who in any way have manipulated the game to gain unearned advantages from others.

Representational strategies and self-referentiality in video games have indeed become more sophisticated, and reading this sophistication as an index of the medium's overall maturation seems cogent. Metalepsis in video games runs the gamut from mundane to avant-gardist. Still, mainstream video games demonstrate a proclivity toward nondisruptive forms of metalepsis. For example, *Super Mario Odyssey* (2017), a 3-D action platformer, includes recurring sections in which players control a 2-D,

9-bit Mario sprite, complete with MIDI-format music and side-scrolling control scheme. The frame breaking here does not further direct the in-game narrative, nor does it disrupt gameplay in a way that defamiliarizes gaming as an activity; nevertheless, these sections call up and reflect on the legacy of the *Mario* franchise and presume players' familiarity with the 1980s graphic aesthetic and design principles. *Rhetorical* and *ontological* remain useful heuristic parameters for assessing the narrative quality of such ergodic metalepsis. However, we will need to expand our vocabulary to account for the machine and player extradiegetic actions that are also part of any gaming experience (cf. Galloway 2006) and therefore may become part of metaleptic reference.

Metaphor

The notion of metaphor has been used with regard to computer games since computer games were first analyzed as objects of scholarly study. Metaphor can be applied to contexts of game reception as well as game production.

In the context of game reception, concepts and instances of metaphor are applied to the interpretation and

interpretability of games. When computer games were first considered narrative, authors mused about how graphically abstract games with little to no narrative content might possibly be interpreted. A prime example is Janet Murray's famous reading of the abstract game classic *Tetris* (1984), which she interpreted as a metaphor for the busy working life of American office workers in the 1990s (Murray 1997, 144). This implies that computer games are texts; on the other hand, this can be considered not as an interpretation of a game object but of an individual gameplay experience. Metaphors may help players to make sense of their own gameplay experiences and assist when telling others about it. A player-narrative metaphor can be effective when conveying a *Tetris* gameplay experience to others without having to describe each gameplay individually.

From an aesthetical perspective, graphically abstract computer games are commonly characterized as metaphorical, whereas games with photo-realistic graphics and depictions of characters and events are regarded as simulations (Möring *Games and Metaphor* 2013; Möring "Metaphor-Simulation" 2013). The game *The Marriage* (2007) is considered metaphorical (Juul 2007; Rusch 2009; Bogost 2011) because it mimics the dynamics of a couple's love relationship, with both partners depicted as squares of changing sizes, opacity, and location, depending on the player's success in caring for the relationship. At the same time, playing a love relationship in *The Sims 3* (2009) would be identified as a simulation of love because the game is widely considered a life simulation. Both metaphor and simulation are—contrary to popular belief—simultaneously characterized by

the similarity and dissimilarity between the *source system* and *target system* of simulation as well as the *source domain* and the *target domain* of metaphor. Their existence as both simulation and metaphor create this similarity and dissimilarity in the first place, and, thus, definitions of simulations and metaphors share significant similarities. *Metaphor* is defined as “a device for seeing something in terms of something else. It brings out the *thisness* of a *that*, or the *thatness* of a *this*” (Burke 1941, 421–422). And “to simulate is to model a (source) system through a different system” (Frasca 2003, 223). However, cognitive metaphor theory allows understanding of the similarity of the underlying metaphorical model of love in both cases, *The Marriage* and *The Sims 3* (Möring 2015). Although the games are visually dissimilar, they both model love in terms of a general cognitive model of love that is metaphorically structured.

The concept of metaphor has found some prominence among game designers, who often develop specific schemes of interaction around a metaphor. This could be the mapping of movements of game characters onto game controllers in sports games or action-adventure games, allowing users to cognitively connect the input hardware they use with a game’s on-screen action (Kayali and Purgathfer 2008). Interface metaphors and mental models are established concepts in the field of interaction design, which has a strong influence on game design.

Analogous to poetry and the arts, metaphor is an effective means of expression among designers of art games and those who subscribe to the paradigm of proceduralism, which is the way art games express meaning, as opposed to

persuasive games, which apply procedural rhetoric (Bogost 2011). *The Marriage*, often identified as metaphorical, is also an art game, and according to its author, Rod Humble, “intended to be art” (Humble 2006). The same goes for Jason Rohrer’s game *Passage* (2007), which is simultaneously interpreted as a “very abstract metaphor . . . for the human condition” (Dahlen 2010) and applying proceduralism (Bogost 2011).

Some authors find that most metaphorical readings of games interpret them in terms of existential metaphors such as the human condition, death, life, work, and love. They argue that it is not because game designers applied proceduralism to achieve a metaphorical expression of their game but because the computer game’s form is itself existential, and it is the choice of the medium that gives rise to such existential metaphorical readings (Möring *Games and Metaphor* 2013). Other authors, such as Doris Rusch, oppose this idea and argue that it is possible to design meaningful games by leveraging myth and ritual and experiential metaphors (Rusch 2018, 2017). Experiential metaphors create “an analogy between gameplay and real-life experience evoked by what the moment-to-moment gameplay feels like, whether these analogies were intended by the designers or not” (Rusch 2017, 74). To Rusch, the grappling hook sequence in *God of War II* (2007) is an experiential metaphor for the existential experience of transition, which is described as “letting go and moving on” (Rusch 2017, 75). In a similar spirit, Sabine Harrer investigates game design as a therapeutic method to help people deal with experiences of loss and grief by applying “metaphorical modelling” (Harrer 2018, 196). As a result,

grieving mothers design game worlds, characters, and events that help them express their feelings regarding their loss.

Metatextuality

Metatextuality describes the ability of video games to be able to refer to their own status as systems of signs and rules. Thinking about metatextuality in video games might immediately raise the question as to how far they can be understood as texts. In a broad cultural studies sense,

a text can be defined as “any organized set of discourses (and meanings)” (Lewis 2008, 403) or, slightly more specifically, as “a group of entities, used as signs, which are selected [and] arranged . . . to convey some specific meaning” (Gracia 1995, 4). Accordingly, *metatextuality* indicates ways in which video games refer to their own status as mediated, as artifacts, as constructed, or as systems of signs—in other words, a video game knowing and displaying that it is a video game.

Metatextuality exists next to similar terms, such as *metareference* and *metafictionality*, and related concepts, such as self-reference, self-reflexivity, and self-awareness. In the most general sense, following Wolf (2008), metareference can be seen as a “special variant” (303) of self-reference, one that “always implies an awareness of the medial status of the work or system under consideration” (306). *Metatextuality*, in turn, highlights a game’s awareness as part of a larger and complex system of signs, pointing to the ludic, simulational, narrative, and fictional elements, among others, that make up how a video game can be understood as a kind of text. More detailed (often narratological) terminological differentiations between these concepts have previously been discussed (cf. Wolf [2008]; Nöth [2008]), whereas the functions and effects of (and reasons for) the use of metatextuality in video games have received comparatively little attention. In fact, in contrast to the prominence of metatextual elements in video games, the subject has been relatively rarely studied so far, unlike media forms such as the novel (cf. Waugh [2002]; Currie [2014]) or the medium of film (cf. Stam [1992]; Ames [2015]).

To understand the variety in which video games feature metatextuality, it is useful to

further specify it in two ways. The first concerns the realization that metatextuality is not a binary characteristic—it is not a question of a video game either being metatextual or not—but a matter of degree (cf. Waugh 2002, 14; Nöth 2008, 13; Wolf 2008, 304), something that video games can engage in, with one game potentially being more metatextual than another. As Wolf notes, “‘metareference’ is first and foremost applicable to individual phenomena within certain works (‘metaelements’). Yet, if metaphenomena become salient features of a work as a whole, one may speak . . . of a ‘metatext’” (307). In *Max Payne* (2001), for instance, a dream sequence has the main character explicitly state that “[he] was in a computer game,” a metatextual realization that is explained by the drugged-up status of the protagonist (Walther 2008, 233–234). In contrast, games such as *The Beginner’s Guide* (2015) and *Pony Island* (2016) insist on an engagement with their status as fictional games as the core premise of the playing experience. This degree can thus also be influenced by a specific metatextual reference being (more or less) explicit, only being hinted at, or having to be interpreted and inferred (Jannidis 2009, 546).

Second, because video games are such complex systems of signs, they can implement metatextuality in regard to different elements of their textuality. Previous studies have included systematizing efforts for some of these aspects (cf. Walther [2008]; Santaella [2008]; Carrasco and Tosca [2016]), yet these largely differ according to scholars’ ontological understanding of video games. In a most general sense, all video games are inherently self-aware and self-referential, “since playing and games create their own self-referential worlds apart from the world of referential facts and realities” (Nöth

2008, 13; cf. also Walther 2008) and since “the rules of a game *generally* refer back to the game as a game” (Rapp 2008, 255). However, beyond this aspect, video games can also exhibit more “*explicit forms*” (Rapp 2008, 255) of metatextuality. These different forms and ways in which metatextuality can be implemented often intersect and overlap.

One kind of metatextuality concerns video games’ rules, for instance, when part of a tutorial is addressed simultaneously to the protagonist and the player, as in games such as *Zork* (1977) and *Metal Gear Solid* (1998) (Neitzel 2008, 244–249). Another kind relates to video games’ fictional worlds, in which “images, texts, films, or spoken language” (Jannidis 2009, 545) can explicitly include a reference to the game as an artifact, as in *Max Payne* or *Pony Island*. A game within a game, such as *Day of the Tentacle* (1993), which features a playable copy of its predecessor, *Maniac Mansion* (1987), accessed through a computer in the game (Rapp 2007, 260), exemplifies a combination of both rule-based and fictional metatextual elements. Moreover, metatextuality can refer to a variety of (extratextual) aspects that form part of the playing experience, such as the specific (fictional) game itself, its materiality (i.e., the hardware), the act of playing, the presence of the player, or video games and playing in general, among others.

Many of the strategies with which video games implement metatextuality have been remediated (cf. Bolter and Grusin [2003]) from older media, such as metalepsis, mise-en-abyme, or the breaking of the “fourth wall,” which are usually adapted to fit the specifics of the video game medium (Carrasco and

Tosca 2016, 34). Intertextual references, including those to a game’s genre or to other media (Jannidis 2009, 544), can also (but do not have to) lead to metatextuality, for instance, in a game such as *Alan Wake* (2010), whose frequent references to novels, films, and TV series also highlight its own mediality as a game along with its efforts to engage in trans-medial storytelling (cf. Thon 2016).

The functions and effects of metatextual elements in video games vary and have changed over time. While existing studies often cite humor or entertainment (Carrasco and Tosca 2016, 33; Jannidis 2009, 557) as primary functions, this might be particularly applicable only to singular metatextual instances in video games, including so-called Easter eggs (Jannidis 2009, 546). More thoroughly, metatextual games exude more complex pleasures as well, such as an interest in “operational aesthetics,” that is, a pleasure inherent in the formal aspects of a game instead of just its content, with players “watch[ing] the gears at work, marveling at the craft” (Mittell 2015, 43). All of these functions highlight that metatextuality also centrally depends on being recognized by players (Wolf 2008, 307), rather than only being a static element of a video game. Additionally, some contemporary video games use their metatextual elements to probe their inner workings (Schubert 2019). For instance, *The Stanley Parable* (2013) is essentially about the difficulties of narrating a linear story in a video game balanced against the expectations of agency on the side of players (Fest 2016), reflecting parts of the central debate between *ludologists* and *narratologists* in early game studies. Similarly, both *BioShock* (2007) and *BioShock Infinite* (2013) feature metatextual

narrative elements that point out the inherent lack of “freedom” of choice players have had while playing these games (Jannidis 2009, 560–561; Schubert 2015). Comparable to metafiction that “pose[s] questions about the relationship between fiction and reality” (Waugh 2002, 2), such sophisticated metatextual engagements thus highlight core questions about the nature of video games.

Overall, *metatextuality*, as an umbrella term, captures the different ways in which video games can highlight their own constructedness. Researching metatextuality in video games seems particularly productive when examining the different ways in which games can refer to themselves as systems of signs while acknowledging metatextuality as a gradable concept. As video games continue to increasingly experiment with their form, probing more deeply into the poetics and the cultural work of their metatextual elements, both theoretically and in individual case studies, appears to be a promising avenue for future studies.

Metroid Series

Metroid is a single-player action-adventure game for the Nintendo Entertainment System (NES)/Family Computer. Released in August 1986 in Japan, August 1987 in North America, and January 1988 in Europe, it is the first game in Nintendo's *Metroid* series. It was designed by Yoshio Sakamoto and Hirofumi Matsuoka and was developed by Nintendo's famed Research and Development 1 (R&D1) division under the supervision of Gunpei Yokoi.

The game's backstory, inspired by Ridley Scott's *Alien* (1979), revolves around the titular metroids, mysterious life-forms endowed with highly destructive capabilities. Transported to Earth on board a Space Federation research vessel, the metroid specimens are captured by pirates and taken to planet Zebes. There, in the safety of their fortress, the pirates proceed to replicate the creatures with the intention of using them as a biological weapon. Following an unsuccessful assault on the planet, the Space Federation dispatches a lone warrior, cybernetically enhanced bounty hunter Samus Aran, to infiltrate the pirate stronghold and eliminate the threat.

Metroid's gameplay focuses on exploration and combat, as the player navigates the sprawling underground fortress, fighting assorted enemies along the way. The game takes cues from Nintendo's successful earlier titles, combining side-scrolling platform-based design popularized by the seminal *Super Mario Bros.* (see *Mario Series*) with the open-ended world and nonlinear progression of *The Legend of Zelda* (see *Legend of Zelda, The Series*). Unlike typical platform games of the time, which forced the player to traverse the world from left to right, one level at a time, *Metroid* allows movement in all directions. Its labyrinthine map, combining horizontally and vertically oriented areas, is designed with free-form exploration and backtracking in mind: scattered around the pirate fortress are a number of upgrades for Samus's combat suit. The player must locate and collect these permanent power-ups to reach previously inaccessible areas and progress in the game.

In addition to its intricate map design, *Metroid* has often been praised for its

The cartridge for *Metroid II* for the Nintendo Game Boy. (Michel Bussieres/Dreamstime.com)

somber and claustrophobic atmosphere (especially compared with earlier NES titles), and Hirokazu Tanaka's haunting musical score. The game is also notable for its protagonist, bounty hunter Samus Aran. Created by Makoto Kanom and designed by Hiroji Kiyotake, she is one of the first video game heroines. Interestingly, her gender is not immediately obvious. The Japanese and English instruction manuals consistently refer to Samus using non-gender-specific and masculine pronouns, respectively, and her bulky armor suit makes it all but impossible to determine whether the character is even human. Her true identity is only revealed once the game is completed in less than five hours, whereupon she removes her helmet, displaying a mane of long, auburn hair. The inclusion of multiple endings, dependent on the time and degree of completion (items

collected, secrets found, etc.), has since become one of the staples of the series.

The game was originally developed for the Nintendo Family Computer Disk System—an external floppy disk drive that plugged into the Famicom cartridge port. Taking advantage of the rewritable medium, this version could save up to three games to the disk. In the cartridge-based conversion, released in 1987, this functionality was replaced with a password system, allowing users to resume play from a specific point.

The *Metroid* series is one of Nintendo's longest-running and most profitable franchises. The first game was followed by three direct sequels, *Metroid II: Return of Samus* (Nintendo Game Boy, 1991), *Super Metroid* (Super Nintendo Entertainment System [SNES], 1994), and *Metroid Fusion* (Game Boy Advance, 2002), all developed by Nintendo's R&D1. In the early 2000s, the *Metroid* license was offered to the American developer Retro Studios. In a controversial but ultimately highly successful move, Retro departed from *Metroid*'s two-dimensional roots, creating instead a trilogy of first-person action adventures: *Metroid Prime* (Nintendo GameCube, 2002), *Metroid Prime 2: Echoes* (Nintendo GameCube, 2004), and *Metroid Prime 3: Corruption* (Nintendo Wii, 2007). In 2009, all three games were rereleased as *Metroid Prime Trilogy* (Nintendo Wii). The limited edition compilation included new versions of *Prime* and *Echoes*, featuring updated graphics, motion control, and support for wide-screen televisions. The next entry in the series, *Metroid: Other M* (Nintendo Wii, 2010), was developed by Team Ninja (of the *Ninja Gaiden* fame). Drawing on the two strands of the franchise's history, it

combines third- and first-person perspective gameplay. A series spin-off, *Metroid Prime: Federation Force* (2016), was a four-player game released for the Nintendo 3DS, and in June of 2017, *Metroid Prime 4* was announced for the Nintendo Switch. An enhanced remake of the original game was released in 2004 for the GameBoy Advance under the title *Metroid: Zero Mission*.

Mexico

Mexico is a video game giant; as of late 2018, the industry boasts a market value of \$1.07 billion and a player base of forty-four million Mexicans, over a third of the population. Video games and Mexico have always had a loving relationship. In the early days, when there was no legal way to acquire consoles, a gray market for illegally imported home *PONG* consoles and arcade machines blossomed. For a while, there was even a bootleg version of *PONG* (1972), called *NESA-PONG*, developed by local engineer Morris Behar.

In the 1980s, the first legal shipment of Atari consoles arrived in Mexico, and during that decade, the market saw the greatest growth, as did the arcade scene. The market was big enough for companies such as Capcom, SEGA, and SNK to open local offices in the country; the influence of those days is still felt throughout all of Mexico, with the *Street Fighter* and *The King of Fighters* series remaining some of the most popular games in the country, and it is not uncommon to even find arcade cabinets in rural areas.

In 1985, the Nintendo Entertainment System (NES) launched, but due to its high price tag, it was inaccessible to most Mexicans; but thanks to the work of Teruhide Kikuchi, Nintendo soon exploded in popularity in the country. Kikuchi worked for C. Itoh, the official Nintendo distributor in the region; he opened up Mundo Nintendo ("Nintendo World") retail stores, where players could try out the latest releases, and he spearheaded initiatives such as the *Club Nintendo* magazine and the *Nintendo Maniacos* TV show. Through these initiatives, Kikuchi drilled the Nintendo brand into Mexican popular culture to the point that, even today, a lot of people refer to any video game console as a "Nintendo." And if you could not afford an NES console, you could afford a magazine or watch the TV show and be part of the Nintendo community in the country.

Through the life cycles of the NES, SNES, and Nintendo 64, Nintendo dominated the video game market, but the time came when audiences started asking for more mature experiences, and it was through the PlayStation 2 (PS2) that Sony managed to get a foothold in the Mexican market. The PS2 was the Mexican champion of the sixth-generation

consoles, but with a heavy marketing push, the opening of local offices, and the huge *Gears of War* and *Halo* communities that started brewing in the country, the crown was stolen by Microsoft during the seventh generation of consoles: the Microsoft Xbox 360 was the most popular console of those years.

While Mexico has been a giant in video game consumption, game development has been more of a struggle. There have been many attempts to kick-start an industry in the country, but the results have been mixed. This industry has always been ignored by the government, and even when little support has come its way, it has been lost due to corrupt processes that end up assigning funds to the friends or family of the government official in charge of the funds. The goal of creating a Mexican video game development industry has always been in the hands of the fans.

For the first serious game developers in the country, it all started with *Club Nintendo* #44, an issue that included a report on Digipen. This was the first time that fans realized their hobby could be also a career. The first formal game studios in Mexico were Aztec Tech Games (founded in 1998), Evoga (founded in 2000), and Radical Studios (founded in 2000). Evoga did art outsourcing for SNK, and both Aztec Tech and Radical Studios worked on games that never saw the light of day; however, their experience would help the next generation of game developers to avoid their mistakes.

The next big studio in the country was Sabarasa, founded in 2009. The studio worked with licenses and managed to ship games based on huge Mexican intellectual properties (IPs) such as “Atrevete a Soñar” and “El Chavo del Ocho.” The

studio tanked when its biggest investment, a *lucha libre* title based on the AAA Mexican league, tanked.

Today, the Mexican independent industry is at its highest point so far, and still without government support. Studios such as Bromio, HyperBeard, and Lienzo have managed to create sustainable businesses through the creation of original IPs.

Bromio grew up in the mobile game market with games such as *Take Your Time* (2014) and *Mighty Swiping Shiba Force* (2015), but it really struck gold when it launched a successful Kickstarter campaign for *Pato Box* (2018), a spiritual successor of *Punch-Out!!* (1984) with a crime noir narrative that goes to unexpected places. It was declared Indie Game of the Year by Goichi Suda (known by the nickname “Suda51”) in his monthly *Dengeki* magazine column.

Lienzo is another studio that found its claim to fame through Kickstarter, successfully finding funding for *Mulaka* (2018), a *Zelda*-like game where you play as a Tarahumara (a group of indigenous people living in the state of Chihuahua in Mexico). The game is both a fantastic, fun, and engaging video game and a digital artifact of immense cultural value for the Tarahumara culture.

Another great example of Mexican creativity and success is HyperBeard studios, a mobile game developer with years of experience. The studio is mostly known for *Kleptocats* (2018), without a doubt the most successful new Mexican IP of recent years. The franchise has animated shorts, two games, a book, and a merchandising deal with toy company Funko.

As long as the government continues to ignore the industry, it will be hard to

create a sustainable infrastructure; however, small developers are starting to find success in the country, and a new generation of games is about to come out. *Broken Reality*, *Design Hero*, and *Neon City Riders* are examples of Mexican creativity with international appeal. The Mexican indie game development community has never been as vibrant nor successful as it is today. If these brave warriors keep on moving forward, the day when the country has a sustainable industry may come soon.

MicroProse

MicroProse was a prominent developer and publisher of computer games in the 1980s and 1990s, releasing long-running franchises such as *Civilization*, *X-Com*, and *Master of Orion*. Businessman J. W. "Wild Bill" Stealey and game designer Sid Meier were employees at electronics company General Instruments when they founded the game company in 1982 as a side venture. The well-propagated founding myth is that Meier, a rather reserved programmer, caught the attention of Stealey, a colorful former fighter pilot, in an arcade gameplaying session in which the former won not through reflexes but by noting the game's predictable artificial intelligence (AI) patterns.

In more in-depth interviews, Meier has presented a somewhat less dramatic account, but it is a good characterization of the two's partnership. Stealey was the flamboyant promoter and managed all the business decisions, and Meier was the low-key game-making genius.

All of the company's offerings in the 1980s, such as *F-15 Strike Eagle* (1984), *Silent Service* (1985), and *Gunship* (1986), were focused on the new and steadily growing home computer market. Within a year of its founding, the company was successful enough that the cofounders quit their positions at General Instruments. MicroProse expanded into the distribution of other developers' games and also focused on European markets, an unusual emphasis in the early American computer game industry. Eventually, the company had development studios in Chipping Sodbury, England; Alameda, California; Chapel Hill, North Carolina; and Hunt Valley, Maryland. In the early 1990s, Stealey decided to invest in arcade games and console-based games. Meier was uncomfortable enough with these moves that he sold his stake in the company to Stealey but continued to work as a contracted game designer. The combination of the risky new ventures and the recession of the early 1990s put MicroProse in financial trouble, leading to an initial public offering (IPO) to raise cash. This did not solve the problems, and in 1993, Stealey persuaded Spectrum Holo-byte to purchase MicroProse.

The change in management caused discontent and led to a series of departures by key personnel. In 1995, Bruce Shelley left, eventually founding Ensemble (maker of the *Age of Empires* series). In 1996, Sid Meier, Jeff Briggs, and Brian Reynolds left to found Firaxis, which

went on to make *Sid Meier's Alpha Centauri* (1999) and the most recent editions of *Civilization* (*Civilization III* in 2001, *Civilization IV* in 2005, *Civilization V* in 2014, *Civilization VI* in 2016, and *Revelation* in 2007), *Sid Meier's Pirates* (2004), and *Sid Meier's Railroads* (2006), among other titles. With these changes and the acquisition of MicroProse/Spectrum Holobyte by Hasbro Interactive in 1998, the traditional identity of the company effectively disappeared. French game industry giant Infogrames purchased Hasbro Interactive in 2001, which ended the existence of MicroProse as a label. Some of the studios distributed by MicroProse lasted a few more years, but these eventually shut down as well.

MicroProse was an important force in video game history because of the well-known games it created and the influential people who worked for it. In its early days, the company focused on military simulations—either arcade-style, such as *Gunship* (1986), or strategic map-style, such as *NATO Commander* (1983)—which sold well but were neither huge hits nor deeply influential. The 1987 release of *Sid Meier's Pirates* was both a significant success and departure in style because it was a kind of role-playing game (RPG); it also marked the first use of Meier's name as a marketing tool. Meier and Shelley continued to develop outside the purely military theme with *Railroad Tycoon* (1990) and the blockbuster hit *Civilization* (1991). Although Stealey was more interested in the purely militaristic games, it was the empire building strategy games that became the distinctive hallmark of MicroProse in the 1990s, such as *Colonization* (1994), *Masters of Magic* (1994), and *Masters of Orion* (1995). Other prominent series include

the tactical battle *X-COM* games (developed by Mythos Games) and a wide range of flight sims, such as the *Stealth Fighter*, *Gunship*, and *Falcon* games.

Many MicroProse employees went on to successful careers elsewhere. In addition to Meier, the list includes Bruce Shelley, designer of *Age of Empires* (1997); Brian Reynolds, cofounder of Firaxis Games and later Big Huge Games; and Jeff Briggs, cofounder of Firaxis Games. Dan Bunten, the designer of *Seven Cities of Gold* (1984) and *M.U.L.E.* (1983), also worked for MicroProse for a few years.

Microsoft Studios. See Xbox Game Studios

Microsoft Xbox

The Xbox is a sixth-generation console produced by Microsoft. The console was first announced in 1999 and was released in November 2001 in North America and early 2002 in other markets. The Xbox was the first game console to be entirely

produced by Microsoft. It takes its name from the DirectX software package developed for the use of multimedia (particularly games) on the various Microsoft Windows platforms. After the seventh-generation Microsoft Xbox 360 was released in November 2005, the original Xbox was discontinued in 2005, and new software was gradually phased out of production; the last title was released in 2008.

The Xbox featured a significant number of technical innovations: a Pentium III microprocessor, graphics and sound processors codeveloped in a troubled partnership with graphics specialists Nvidia (the partners were involved in a legal dispute over the pricing and supply in 2002–3), an 8-gigabyte hard drive, and an Ethernet connection for LAN and online play. From November 2002, its internet connectivity was supported by the Xbox Live service, which allowed software and updates to be downloaded directly to the Xbox and stored on its hard drive. The Xbox Live service supported downloadable content and online multiplayer access for Xbox games until April 2010. Xbox Live subscribers had either a Silver membership (free but limited access) or a Gold membership (fee-paying but full access). Games and downloadable content were purchased with Microsoft Points, which could be added to a subscriber's account through store-bought prepaid cards or online via credit card. The service allowed for the publication of download-only games through the Xbox Live Arcade.

This service proved popular, with more than three million games purchased by February 2006. Bizarre Creation's *Geometry Wars* (2003), originally included as a minigame in *Project*

Gotham Racing 2 (2003), was made available for individual download and became the Xbox Live Arcade's most popular title. Other popular downloadable games were puzzle games such as PopCap Games' *Bejeweled 2 Deluxe* (2005) and various repackaged arcade games from the 1970s and 1980s. By 2007, Xbox Live was available in twenty-six countries, primarily in North America (including Mexico), Western Europe, Scandinavia, and select parts of the Asia-Pacific: Australia, India, Japan, Singapore, New Zealand, South Korea, and Taiwan.

Like the Sony PlayStation 2 (PS2), the Xbox has an internal DVD-ROM drive, although it could not be used to view DVDs without the additional purchase of a separately packaged, specialized DVD remote. The DVD-ROM drive was used to play games or music, the latter of which could also be stored on the hard drive in MP3 format. This feature was explored in a number of games—including the launch title, Indie Built's *Amped: Freestyle Snowboarding* (2001)—that allowed songs stored on the hard drive to be used as the game's soundtrack. The original Xbox retail package also came with a single controller, which, as of 2019, is the bulkiest controller released for a console system. This controller was widely criticized and eventually replaced with a smaller, lighter controller that had originally only been included in the Japanese Xbox retail package.

The Xbox console developed a considerable modding community, primarily to circumvent the digital rights management (DRM) systems that were built into the hardware and software of the console. Modders also experimented with developing other software for Xbox, including XBMC (Xbox Media Centre), which

enabled the Xbox to act as the hub of a home entertainment system, and a port of Linux for Xbox that allowed the console to function like a desktop computer.

When the console was launched, Microsoft was criticized for the poor quality of several of the launch titles, particularly Adrenium Games' *Azurik: Rise of Perathia* (2001). Microsoft's successful acquisition in 2000 of game developer Bungie, who had developed successful games, including *Marathon* (1994), for the Macintosh computer in the 1990s, meant that the studio's next title, *Halo: Combat Evolved* (2001), would be an Xbox exclusive. The popularity of the game ensured the success of the Xbox, and the protagonist, Master Chief (voiced by Steve Downes), became the console's unofficial mascot. The importance of the game series to the console's fortune was cemented with the release of *Halo 2* (2004). Promoted by the celebrated alternate reality game (ARG) *I Love Bees* (42 Entertainment, 2004), *Halo 2* made more than \$125 million in sales during its first twenty-four hours and went on to sell more than eight million units, becoming the best-selling title for the console.

By the time its production was discontinued, the Xbox had sold approximately twenty-four million units: sixteen million in North America, six million in Europe, and two million in Asia. It secured an impressive share of the local North American console market, overtaking Nintendo GameCube in sales and second only to the PS2. The Xbox also met with some success in Europe but did not do as well as anticipated in Japan. Initially, Microsoft had difficulty brokering deals with established software producers, which meant that in the first few years of

the console's production, many key titles were released as PlayStation exclusives or the Xbox version was only released after considerable delay. However, the Xbox versions of a number of multiplatform franchises sold over a million units, including Grey Matter Interactive's *Call of Duty 2: Big Red One* (2005), Electronic Arts/Black Box's *Need for Speed: Underground 2* (2004), and Ubisoft Montréal's *Tom Clancy's Splinter Cell* (2002). A number of Xbox-exclusive titles also garnered commercial and critical success, among them *Halo: Combat Evolved*, *Halo 2*, and the role-playing games (RPGs) *Fable* (2004) and *Star Wars: Knights of the Old Republic* (2003).

Microsoft Xbox One

The Xbox One is an eighth-generation console produced by Microsoft. The console was first announced in 2011 and was released in November 2013 in North America and most other markets. Notably, the Xbox One was released in China in September 2014. The name of the console was selected to be consistent with the branding and marketing of the device as an "all-in-one entertainment system."

The Xbox One was initially bundled with an updated version of the voice- and motion-activated Kinect, which had first been released in 2011 as an add-on for the Xbox 360. However, by 2014, a reduced-priced console without the Kinect was also available. As part of the “all-in-one” package, the Xbox One emphasized the integration of cloud computing, social networking, and livestreaming. The console provided a suite of recording and editing options as well as links to Twitch and other streaming services.

A streamlined Xbox One S was released in 2016, followed by the deluxe Xbox One X in November 2017. Both of these new versions of the Xbox One console had been updated to playback video and render games at 4K resolution.

Prior to the release of the Xbox One, a rumor circulated that it would be an “always on” system, and there was a great deal of consternation about what this suggested for digital rights management (DRM) on the system. On release, the game licensing scheme for Xbox One was elaborate and required all games to be bound to the user’s Xbox Live account. Microsoft promoted this feature as “flexible,” as it allowed people to access their games from any other Xbox One console. However, this also meant that each Xbox One would be required to connect to the internet once every twenty-four hours or all games would be disabled until it was reconnected. This DRM scheme was regarded very negatively by consumers. In response, Microsoft changed the Xbox One’s DRM policy, particularly the need to connect to the internet, and also removed the requirement that the Kinect sensor always be active and connected. This later requirement had also

become a flashpoint of concern for privacy advocates. In general, the focus Microsoft had placed on the multimedia capacities in the initial phases of the promotion of the Xbox One also drew negative attention from some consumers who expected the focus to be on games.

The Xbox One featured many innovations. For example, the Xbox Adaptive Controller, a special controller designed for users with disabilities, was released in 2018. The controller features two large, raised buttons and a series of connectors to which a variety of peripherals can be attached that replace the functions of the standard Xbox controller buttons. Another crucial innovation was the Kinect 2.0, a natural user interface sensor that allowed the console to be controlled through motion tracking and voice commands. The Kinect 2.0 could track up to six people simultaneously.

The Xbox One launch was accompanied by an updated and upscaled Xbox Live service that used over three hundred thousand servers. Xbox Live members now had access to cloud storage, which was available to save various media as well as games and save files. In 2016, social networking features were added. “Clubs” allows members to join groups focused on specific interests or games, and “Looking for group” (LFG) helps members locate other players for multiplayer games. Xbox Live members can feature recorded clips on their Xbox Live profile page. Most features initially required a Gold subscription to use, but since June 2014, Gold membership has no longer been required for basic services; instead, the subscription gave members access to a small collection of free games each month. Sociological

studies of the Xbox Live environment raised considerable concerns about the lack of moderation in multiplayer environments, where harassment and hate speech against women, people of color, and genderqueer players were alarmingly common.

Xbox One games are physically distributed on Blu-ray discs and are also available as downloads through the Microsoft Store. The best-selling Xbox One game is 343 Industries' *Halo 5: Guardians* (2015), which has sold over five million copies. Other high-selling titles, each of which has shipped over a million copies, include Microsoft Studios' *Forza Motorsport 5* (2013), Mojang's *Minecraft: Xbox One Edition* (2014), Infinity Ward's *Call of Duty: Infinite Warfare* (2016), EA Vancouver's *FIFA 17* (2016), and Turn 10 and Massive Entertainment's *Tom Clancy's the Division* (2016). Also among the best-selling titles was the indie game *Cuphead* (2017) by StudioMDHR.

The Xbox One sold rapidly on release, selling over one million units in the first twenty-four hours it was available. More than forty-five million had been sold worldwide by the middle of 2019. Despite this, very few sales have been made in Japan (estimated at approximately fourteen thousand total sales).

Microsoft Xbox 360

The Microsoft Xbox 360 is a seventh-generation home video game console. In development since early 2003, the system was officially unveiled during an MTV special event on May 12, 2005, and released in North America on November 22, 2005; in Europe on December 2, 2005; and in Japan on December 10, 2005. The second game system developed by Microsoft Corporation's Entertainment and Devices Division, the 360 is a successor to the original Microsoft Xbox.

The console's custom PowerPC-based "Xenon" central processing unit (CPU), designed and manufactured by IBM, is a triple-core processor, with each core operating at the speed of 3.2 GHz. Shared between the cores is 1 MB of on-die Level 2 cache memory. Graphics are handled by the 500 MHz ATI Xenos chip (also doubling as a northbridge). The system is equipped with 512 MB GDDR3 RAM, shared between the CPU and graphics processing unit (GPU). The Xbox 360 supports multichannel surround sound and wide-screen high-definition graphics, up to 1080p. Broadband connectivity is provided by the built-in 10/100 Ethernet adapter (or, for the S model, a built-in wireless network adapter). As the first high-definition (HD)-capable console on the market, the 360 set the unofficial standard for the current generation of HD gaming technology.

The Microsoft Xbox 360 console system. (Jovani Carlo Gorospe/Dreamstime.com)

A DVD-ROM drive is the system's primary mass storage device. An external HD DVD drive was introduced in November 2006 but was discontinued in early 2008, a few days after Toshiba's decision to cede the HD optical disk market to the competing Blu-ray format. An optional detachable hard disk drive can be used to store games, media files, and downloadable content. In the absence of a hard drive, memory cards need to be used to save game data and system settings. Since December 2008, the Xbox 360 Arcade units have been equipped with internal flash memory, eliminating the need for memory cards. Designed as a digital media hub, the Xbox 360 supports local playback and over-the-network streaming of multiple video, audio, and image formats.

The Xbox 360 was initially sold in two retail configurations, as a \$299 Core system (equipped with a wired controller and a standard definition A/V cable) and a

\$399 Pro package (including a wireless controller, an HD A/V cable, a 20 GB hard drive, and a headset). By 2007, the lineup was expanded to include the black-cased Xbox 360 Elite (120 GB hard drive), and the entry-level Core model was replaced by the Xbox 360 Arcade. All these models were discontinued in 2010, following the release of the Xbox 360 S, which features updated internal architecture, expanded connectivity options (built-in wireless adapter, optical audio output, additional USB ports, and an auxiliary peripheral port that is used by the Kinect motion control sensor), and a redesigned, slimmer case. The Xbox 360 S is only available in two configurations: with a 250 GB hard drive or 4 GB of flash memory.

The system is partially backward compatible with the original Xbox games. This functionality is achieved through software emulation and requires the system to be equipped with a hard drive. Emulation profiles are

available for approximately 50 percent of Xbox titles.

Online gaming is supported through Microsoft's Xbox Live subscription service. In addition to providing multiplayer and community features, the service also gives access to the Xbox Live Marketplace, a virtual market giving users access to paid and promotional content, including downloadable games, demos, and map packs as well as (through the Video Marketplace) movies and television show episodes.

Despite the one-year advantage, the Xbox 360 lost its initial market lead to the Nintendo Wii. By January 2011, the system was the second best-selling seventh-generation game console, with over fifty million units sold worldwide (Thorsen 2011), and by June 2014, eighty-four million units had been sold. The Xbox 360 was discontinued April 20, 2016, to make way for its successor, the Microsoft Xbox One.

Middle East

The fast progress of video game culture in the 1970s and 1980s reached Middle Eastern markets at about the same time that it was spreading through households in Japan, the United States, and Europe. Early game consoles were popular in the region, and the senior generation still refers to all kinds of video games as "Atari" games, a result of the dominance of Atari VCS 2600 socially and commercially. Since the introduction of these game consoles and their succeeding 8-bit home personal computers, such as the Commodore 64 and the ZX Spectrum, the demand for video game consoles with an Arabic-friendly interface grew to a high level, encouraging Al-Alamyeh, a Kuwaiti company, to start producing an Arabic home computer called the Sakhr (which means "rock" in Arabic) in 1981, which was essentially based on the well-known Japanese MSX. The product was a success and became popular with middle-class families in the Middle East.

During that time, Al-Alamyeh made an attempt to convert the BASIC computer language into Arabic, and many applications were developed to support domestic users; but in general, the software industry in the region was essentially targeting the corporate applications market. Hardly any of these programs were Arabic video games, and the reason was obvious: no one would invest in a market flooded with cheap pirated

games. Eventually, it was up to the Indie developers to start video game production, such as *War73* developed by Radwan Kasmiya in 1999, and Mohammed Hamza's *Stone Throwers* in 2001. Both were two-dimensional arcade-style games for personal computers and were based on Arab-Israeli conflicts.

The initial success and popularity of these titles stimulate local talents, yet getting investors was another challenge that was settled by bringing oil-rich GCC investments onboard. The first batch of Generation X entrepreneurs established few game studios in Syria, Lebanon, Jordan, and the United Arab Emirates (UAE).

Nevertheless, these studios were unable to depend on video games to survive; competition with international titles, piracy, and closed borders between countries of the Middle East were among the reasons that had forced the majority of these studios to shut down. Survivors had to rely on media production to float, which meant developing CG animations for regional TV channels; therefore, video games became secondary high-risk projects. Still, unique titles such as the *UnderAsh* series (FPS-PC, 2002), *Quraish* (RTS-PC, 2005), and localized titles such as *Arabic Rappelz* (Web-RPG, 2008) and *FIFA 2010* (EA, 2009) found their way to players and enjoyed massive success.

The sociopolitical events that led to the Arab Spring in 2010 put an end to that era, forcing fragile local studios out of business; however, the rise of free-mium client and web-based online games (and mobile games later in 2013) was a dreamlike cure to distribution and piracy problems in Middle Eastern markets. Early adventurous Chinese companies enjoyed a massive success with games

such as *Conquer Online* (ARPG, 2010) by NetDragon Websoft, and their business model was embraced by other Chinese companies. Slowly, it became a heated race to grab a slice of this promising market, where 60 percent of its online users are gamers and its growth rate of 25 percent year after year is the highest in the world. Eventually, regional developers found it beneficial to differentiate themselves in localization; new, culturally relevant content; and innovation. *Knights of Glory* (Web/Mobile SLG, 2011), by Falafel Games, was an example of such a rebirth, with two million installs in the region. Other games paved their way toward international recognition, such as *Pou* (Mobile Pet Game, 2012), by Paul Salameh, with more than five hundred million downloads (2019), and *Revenge of Sultans* (Mobile SLG, 2015), by Onemt, with more than USD 237 million of revenue. Other developers, such as Wafa Games, are trying to create new cross-platform strategy mobile games with *Swords of Glory* (2019), a crusader-themed strategy game bringing real-time strategy (RTS) gameplay to mobile devices through unique gameplay and innovative artificial intelligence (AI) technology.

Even though most success stories in the last ten years (as of 2018) come from mobile games, there are a few courageous independent developers from Egypt and Saudi Arabia who are trying to compete in console and hardcore games with games such as *Badiya* (2016) and *Knights of Light* (2019).

Midway Games

Midway Games, Inc., was an early American video game publisher and developer. The company developed notable titles such as *Mortal Kombat* (1992) and licensed many others, including Taito's *Space Invaders* (1978) and Namco's *Pac-Man* (1980). In 2009, Midway filed for Chapter 11 bankruptcy.

Midway Manufacturing was established in 1958. The company specialized in the manufacturing of amusement equipment, including pinball machines. It was purchased by Bally in 1969. In 1973, Midway became an early developer of arcade video games. Some of Midway's earlier titles include *Asteroid* (1973), *Paddle-Ball* (1973), *Ball Park* (1974), *Basketball* (1974), and *Gun Fight* (1975).

During the 1970s, Midway worked closely with Japanese game developer Taito, with both companies licensing each other's games to their respective countries. In 1978, Midway licensed and distributed Taito's *Space Invaders* to the United States,

which proved to be a great success. In 1980, Midway followed with the release of two additional titles that also proved to be very successful, Williams's *Defender* (1980) and Namco's *Pac-Man*, which was so successful that Midway produced an unofficial sequel the following year, *Ms. Pac-Man* (1981). Midway continued to license arcade games throughout the 1980s, including titles such as *Galaga* (1981), *Joust* (1982), *Robotron 2084* (1982), *Tron* (1982), *Burger-Time* (1982), *Gauntlet* (1985), *Rampage* (1986), and *Xenophobe* (1987).

In 1988, Bally/Midway was purchased and reincorporated by Williams Electronics Games and its parent company, WMS Industries, Inc. Midway continued to produce arcade games under the Bally/Midway label, while producing pinball machines solely under the Bally name. In 1991, Midway absorbed Williams's gaming division and began marketing games without the Bally label. It was during this period that Midway published some of its most popular arcade titles, including *Terminator 2: Judgment Day* (1991), *Mortal Kombat* (1992), and *NBA Jam* (1993). In 1996, WMS acquired Time Warner Interactive, which included Atari Games. Midway changed its corporate name from Midway Manufacturing to Midway Games, Inc. This change also marked Midway's entrance into the home console market.

During this period of time, Midway began to experience financial losses. By 1998, WMS had sold its interest in Midway's stock, making Midway an independent entity. In 1999, Midway left the pinball industry to concentrate fully on video games. In 2001, Midway closed its arcade division due to loss of sales. In 2004, Midway began to purchase multiple independent video game studios in an

attempt to strengthen its development teams. The studio's purchases included Surreal Software, Inevitable Entertainment, Paradox Development, and Rat-bag Games.

Midway continued to face financial hardship, with the company losing millions of dollars in both 2006 and 2007. Afterward, the company began to finance its business with debt offerings. In February 2009, Midway filed for Chapter 11 bankruptcy. By May, Midway had received a takeover bid from Warner Bros. for approximately \$33 million. On July 10, 2009, Warner Bros. purchased the majority of Midway's assets for \$49 million. In August 2009, Midway's San Diego studio was purchased by THQ for \$200,000. Midway's Chicago studio was rebranded NetherRealm Studios in April 2010. The studio is currently overseen by *Mortal Kombat* co-creator Ed Boon and is the primary developer of the *Mortal Kombat* and *Injustice* series of games.

Midwest Gaming Classic (MGC)

With its origins in a convention for fans of Atari's last console, the Atari Jaguar,

the Midwest Gaming Classic (MGC) was cofounded by Dan Loosen, Gary Heil, and Marty Goldberg in 2001 in the basement of Milwaukee's Boy Scout Center. From those humble beginnings, it has grown to become one of the largest fan-based electronic entertainment trade shows in the United States, drawing large crowds domestically and internationally.

Loosen, Heil, and Goldberg first teamed up for the Jagfest 2K1 in Milwaukee, Wisconsin, where they opened the formerly closed Atari-only format to one more inclusive of the industry fan base. When Jagfest moved on to be hosted in another city the following year, they decided to keep the format going under Midwest Classic and expanded it further to include pinball as well. A formal name for the show was finally found after a contest to name it was held, with the winning name picked by future modeling celebrity and fellow Wisconsin native Ben Heckendorn. The name change was accompanied by the final formula for the show: not intended to denote a retro orientation, the "Classic" in the title instead refers to the fact that any game can be considered a classic to someone. Whether released last week or thirty years ago, the games the MGC celebrates span the entire electronic entertainment industry, from past to present.

Currently organized as a two-day show staffed entirely by volunteers, the MGC features a unique combination of events, contests, industry speakers, vending, and more from four main areas: console-based games, computer games, arcade games, and pinball. Being so close to Chicago, once the Mecca of the pinball and arcade industry, the MGC is particularly known for its strong community support in the area, which

regularly features more than two hundred pinball and coin-operated arcade machines, all on free play. The MGC also features the only known fully playable museum with an entire wing dedicated to having every console and personal computer from 1972 to present on display, including imports, all coordinated by Goldberg and *Die-Hard Gamer's* J. D. Norman (diehardgamer.com).

As of 2020, the Midwest Gaming Classic continues to be held in the Milwaukee area.

Military Use of Games

The military use of games includes simulations for training, propaganda, and recruitment as well as gamelike interfaces that correspond to actual events or material. They typically, although not always, feature first-person perspectives, realistic physics, tactical information (the user's position on a map), and, increasingly, photo-realistic graphics.

Militaries have primarily used games for training. This started with simple networked 3-D spaces, such as the U.S. Army's *Panzer* (1977); various simulators developed by Ralph Baer in the late 1970s; *Military Battlezone* (also known as the *Bradley Trainer*), which was commissioned in 1980 and developed from Atari's *Battlezone*; and SIMNET's *Close Combat Tactical Trainer* (1983–90) (Halter 2006). The 1990s saw the rise of aircraft, tank, infantry, and even maintenance simulators that

were much more immersive. Training simulations are now widespread and can in some cases include wargames that take place in entirely virtual realms or that integrate virtual elements with physical elements such as vehicles, aircraft, hired actors, and special effects, such as injuries and pyrotechnics. Combat and surveillance operations have also been conducted through gamelike interfaces (light pens, joysticks, keyboards, televisual displays, etc.). Famous early examples are Project Whirlwind in 1953 (Redmond and Smith 2000) and Operation Igloo White in 1966 (Halter 2006). Current and upcoming uses of gamelike interfaces include systems for remote-controlled aircraft, submersibles, and robotic ground vehicles.

More recently, video games have been used for propaganda and recruitment purposes. The most notable example is the U.S. Army's *America's Army* series (2002, 2003, 2005, 2007, 2009), a free to download first-person shooting game, which is intended to promote the mission and values of the U.S. Army. A countervailing example is Hezbollah's *Special Force* series (2003 and 2007; see "Middle East"). There are also nonsanctioned consumer games that are criticized for promoting the mission or cultural cachet of militarism generally and often the U.S. military in particular (Nieborg 2006).

Although video games and military technologies have always been intertwined, this relationship has evolved in recent years to feature even more fully integrated goals, technologies, and personnel, such that it has warranted some analysts to refer to this relationship as the *military-entertainment complex*. Proponents argue that this nexus can reduce casualties and overall costs. Critics argue

that simulations cannot effectively replicate combat, that there may be antidemocratic implications to media industries directly profiting from war, and that making war more virtual decontextualizes and inoculates against its destructive effects (Der Derian 2009; Stahl 2010).

Minecraft

Minecraft is a sandbox game developed by the Swedish programmer Markus "Notch" Persson and later by the

company he founded in 2010, Mojang. *Minecraft* was released to the public in an early test version in 2009, but the full version of the game was published on November 18, 2011. *Minecraft* is frequently ranked behind *Tetris* (1984) as the second highest-selling game title of all time, having sold 154 million copies as of January 2018. *Minecraft* has also had an immense cultural influence beyond the game itself, leading to merchandising, publishing, and many online channels and vlogs devoted to the game. Mojang and *Minecraft* were eventually sold to Microsoft in November 2014 for \$2.5 billion.

Minecraft has its origins in the earlier *Infiniminer*, a game designed by the American video game programmer Zach Barth in 2009. A much earlier version of *Minecraft* can be seen in a YouTube video posted by Persson titled "Cave game tech test," which coincided with the leaking of the source code for *Infiniminer*.

Minecraft has been released on multiple platforms, including Microsoft Windows and macOS; the gaming consoles PlayStation 3, PlayStation 4, Xbox 360, and Xbox One; the handheld devices PlayStation Vita and Nintendo Switch; and mobile formats such as Android and iOS. *Minecraft* is under continual development, with additional content and refinements to gameplay and art elements supplied in the form of regular patches.

The sandbox world in *Minecraft* is depicted via procedurally generated three-dimensional blocks that can be collected by mining and digging, chopping trees, harvesting plants and animals, and so on. These blocks can be stored in a player inventory; combined to make items such as tools, weapons, and

A large LEGO statue of Alex, the first playable female character in *Minecraft*, holding a diamond sword. (Zayacskz/Dreamstime.com)

furnishings; and placed within the uniform three-dimensional grid that provides the world's structural scaffolding to build an unlimited range of items as diverse as simple homes, entire cities, working machines and computing devices, and pixel art.

In addition to its players' avatars, the world of *Minecraft* is inhabited by a variety of different mobs, including hostile zombies, skeletons and creepers, farm and wild animals of various kinds, and villagers. The mobs have characteristic behaviors, spawn conditions, and drops, and utilizing these is key to accessing many of the key resources in the game. For example, upon its death, a village guardian called an Iron Golem drops a rose and several bars of iron. By constructing a complicated machine out of blocks, the player can "farm" the Iron Golem to produce a continual supply of iron.

The world is also arranged into various geographical *biomes* that have their own characteristic geology, plant life, mobs, and structures. Deserts contain sand and sandstone blocks, cactus, sticks, rabbits, desert monuments, and desert villages (inhabited by villagers). A deep ocean biome includes fish, seaweed, ocean monuments, and their guardians. Furthermore, the world also contains two other discrete areas with their own quite different characteristic features: the lava-filled Nether, accessible only by constructing a nether portal from obsidian blocks, and The End, comprising islands floating in a starless void.

Minecraft has several play modes that alter the difficulty of the game or focus the gameplay on either survival or free creative play. In survival mode, the game begins as the player spawns into a new world equipped only with a map.

Typically, the player must gather resources to survive the first night, when the hostile mobs spawn. Survival mode has easy, normal, and hard settings; among the differences is that easy mode turns off the hostility of the mobs, and hard mode contains *permadeath*: if the character dies at any point during the game, the game world itself is lost. Creative mode frees the player from many of the restrictions of survival mode: blocks are instantly available, and the player can fly around the world.

The gaming objectives of *Minecraft* are largely undefined, and players may choose their own activities. However, several implicit goals can be discovered, and gameplay is often structured around completing the many subordinate goals necessary to achieving these. For example, defeating the endgame Ender Dragon requires travel to The End, which involves discovering the underground stronghold and opening an end portal that can be found there. Both discovering the stronghold and opening the portal require a supply of ender pearls, which must be collected from Endermen in combat (or via some harvesting technique). These further activities require the player to be equipped with weapons and armor, which requires the mining or harvesting of resources.

Individual worlds in *Minecraft* are spawned from numbered seeds, which means that copies of a single world can be generated by different players. Different world sizes are possible, but the PC version allows virtually infinite procedurally generated world sizes. To allow for the display of the expansive world, the world is sectioned into “chunks” that comprise sixteen-by-sixteen block sections of the world that are only generated when the

player approaches them for the first time. Once they have been generated, chunks are saved by the program, but they are only loaded into random-access memory (RAM) when the player is nearby. The spawn chunk—the area where the player initially begins the game—is always loaded into memory.

Minecraft allows for multiplayer worlds, though it utilizes several different methods to do so, depending on platform and version. *Minecraft Realms* is a paid server hosting service that allows players to run multiplayer games. Console-based *Minecraft* usually necessitates that one player host a world that others may join. The console versions of the game also sometimes allow for split-screen gaming.

Several other versions or developments of *Minecraft* have followed from the release of the basic game. *Minecraft Story Mode* (2015) is a narrative-driven game that draws on the art style and thematic elements of *Minecraft*, and *Minecraft Education Edition* (2016) is a version that was developed for educational institutions.

Minigames

A minigame typically refers to a game nested or situated within another game of comparatively larger scope. Given

their small nature, a minigame will often privilege only one mechanic in the pursuit of having a player achieve a “parent” game’s tertiary or voluntary goals. For example, *Spider-Man* (2018) features a series of “signal towers” that are strewn throughout the game’s New York City environment. Upon player interaction, these towers produce an overlay that require a player to align two wavelengths by using the controller’s analog sticks. Successful completion of this minigame across all of New York City’s signal towers results in the full restoration of a network that unlocks a new map view for the player.

Minigames such as these are often contextually situated in their parent game and thus represent a larger action in-game (such as hacking, repairing, crafting, and travel) that may or may not be required for progression along the parent game’s critical path.

A famous example of a noncritical minigame is the card game Pazaak in *Knights of the Old Republic* (2003). This card game can be played in nearly every major city in the game and allows the wagering of in-game credits on the outcome, but it has no effect on the end-game. Some games, such as *Rhythm Heaven* (2008) and the *WarioWare* games, use a collection of minigames as the basis of their overall gameplay.

Minigames sometimes also categorically encapsulate unlockable games that may be bonuses or Easter eggs achievable by a player, such as the “dream sequences” that can be unlocked in *Daxter* (2006) for the PlayStation Portable (PSP). Such sequences allow the player to playthrough a series of Daxter’s dreams between main missions. These sequences tend to use simplified

mechanics, most typically quick time events (matching on-screen button press patterns within a set time limit). Quick time events, made famous in games such as *Shenmue* (1999), are often considered to be reflex-based minigames in and of themselves.

Unlockable minigames may also be previous full versions of games that are smaller than the parent game. In *Ninja Gaiden* (2004) for the Microsoft Xbox, collecting enough scarabs and bringing them back to a store vender allows a player to play the original 8-bit version of *Ninja Gaiden* on an in-game arcade machine.

Finally, it is not uncommon to find “short” games that live outside of larger games that are also referred to as minigames. Such games usually only require a small investment of gameplay time to achieve the game’s primary end state or complete a full game loop, lending themselves well to mobile titles, where players typically have shorter stints available for play. Minigames categorized under this rubric include match 3 variants such as *Threes* (2014) or *Two Dots* (2014), in which levels or rounds are incredibly short (just a few seconds) and a player can drop in or out without loss of progress.

Mixed Reality (MR)

Mixed reality (MR) games, also referred to as *holographic gaming*, combine virtual objects with the real world by anchoring digital environments in the player's physical setting. As the most recent innovation in reality technologies, MR remediates elements of its older predecessors, virtual reality (VR) and augmented reality (AR), combining the interactivity of the former with the pairing of real and digital objects of the latter. Although some debate the difference between AR and MR, and the two terms are often used synonymously, MR is generally distinguished by its focus on interaction between (and not just the copresence of) physical and computer-generated objects. MR games can be divided into two types: as with *HoloTour* (2017), one starts with the real world and overlays virtual elements on it; others, such as *RoboRaid* (2016) and *Fragments* (2017), start with a virtual environment that is shaped by the player's physical surroundings. The former lies further on the spectrum toward AR, while the latter exhibits characteristics of VR, with the key exception that digital objects are superimposed on real ones. Compared to console and PC gaming, MR gameplay shares VR's more intuitive interaction with the game environment through natural interfaces, such as voice commands and head and hand movements. Unlike VR head-mounted displays (HMDs), such as Oculus Rift, MR headsets also scan the user's environment to overlay virtual elements onto the field of vision.

Whereas VR shuts out the real world, MR gameplay takes place in a digitally augmented version of it. *Pokémon GO* (2016) utilizes AR technologies that

originated with photo tagging on Facebook and face filters on Snapchat. Like AR, MR projects holographic mise-en-scène and characters onto the player's actual setting. Apple's *ARkit* (2016) marked a milestone in AR mobile device gaming through its highly interactive holographs. *ARkit 2* (2018) then introduced a multiplayer component, allowing competitors to interact with the same object from their own unique perspectives.

Since the introduction of Microsoft HoloLens through the game *Project X-Ray* (2015), HoloLens has emerged as the leader in MR gaming. Its major achievements include *RoboRaid* (2016), where one's walls are penetrated by invading enemy robots, and *Fragments* (2017), which turns the player's home into a crime scene. In *Zarzl* (2017), players explore a maze in an open space during an alien invasion. While the first two titles can be played at home, *Zarzl* requires a larger open space, such as a parking lot. Recently, public gaming spaces have begun to emerge in converted laser tag arenas that feature MR play in multiplayer games that range from puzzle and exploration-style play to zombie shooters.

As MR is a new format driven by emerging technology, its primary uses and cultural definitions are still very much in flux. In addition to the games previously mentioned, there exists a range of other innovative uses. *HoloTour* (2017), also by HoloLens, enables tourists to view the monuments and ruins they visit through HMDs that provide explanatory digital information. Real footage of the Forum in Rome, for example, is animated with interactive virtual data detailing its multiple archeological

dimensions. This delivery of nonfictional data through highly engaging MR suggests the medium's potential for news-games. Uses of the technology also include educational, business, medical, and military applications. *HoloSurg* (2017), for example, has been used by surgeons to overlay previously captured MRI and radiographic information onto a patient's body during surgery to render visible the obscure bodily interior in the environs of tumors. In addition to developing software for NASA, allowing for collaborative space exploration, Microsoft has also recently won a \$480 million U.S. military contract to develop training simulation software with HoloLens. At this early stage, the MR gaming industry's few startups include *Magic Leap* (2018), which pioneered headsets featuring the first eye-tracking technology to render near objects in sharper definition and set far elements at a greater distance away.

With respect to hardware, PC-connected HMDs provide the most immersive MR experience. Due to the high cost of PlayStation VR, Oculus Rift, and HTC Vive, more affordable stand-alone HMDs have become popular. These products, which include Samsung Gear VR, Google Daydream, and Google Cardboard (the lowest-priced headset on the market) operate with a smartphone inserted in the viewer. HP and Acer developed MR headsets equipped with tracking devices for Windows HoloLens, a milestone innovation leveraging AR's camera/projector function with VR's intuitive interactivity and signature immersive experience.

Mobile Games

Mobile games are games designed to be played on mobile phones or similar portable digital devices. Games designed for handheld game consoles are, however, generally not considered to be mobile games in this sense of the term. As the implementation of games as services and the spread of high-speed networks continues, the *same game* can now be accessible on multiple devices, as the player moves from one screen to another; consequently, the term *mobile games* will grow even fuzzier in the future.

A modern smartphone is effectively a small, network-enabled computer that users trust and carry around with them. Thus, the potential for original, online, and context-aware games implemented for mobile phones appears great, particularly considering that active mobile broadband subscriptions reached 5.3 billion in 2018, and mobile devices had become the most popular gaming platform, passing both personal computers and dedicated video game consoles. Mobile games took a while to reach that potential, however, and the most popular mobile game for over a decade was

Snake (Nokia, 1997) [top] and *Angry Birds Halloween* (Rovio, 2010) [bottom]. (Courtesy of Mark J. P. Wolf)

Snake, a simple arcade-style action-puzzle game, which had been included with popular Nokia handsets since 1997. However, since the 2007 introduction of Apple's iPhone, mobile games designed for the touchscreen quickly became the norm, including such popular games as *Angry Birds* (2009), *Clash of Clans* (2012), and the location-based mobile game *Pokémon GO* (2016).

Nevertheless, for a long time, various technological restrictions, such as small screens and cramped keyboards, kept mobile game design from reaching full maturity. Other challenges included the technological fragmentation of the marketplace, which limited business opportunities and the possibility of original or independent mobile games. With the introduction of user-friendly interfaces

and online market places (e.g., Apple's App Store and Google's Play Store), with their integrated micropayment and digital distribution systems, these barriers have largely been removed. With enhanced technologies and new audiences, the mobile game design space has greatly expanded during the last decade.

Platform fragmentation was another issue that slowed the evolution of mobile games: differences in software and hardware can require game developers to implement hundreds of release versions of a game to reach a critical mass of customers. The mobile operator's role as gatekeeper was another source of fragmentation: in the late 1990s and early 2000s, customers usually received new games through their operator's portal (the "carrier's deck"), and, consequently, individual arrangements with numerous operators needed to be made to have a wide distribution for a mobile game.

Historically, several distinct mobile game ecosystems evolved, each grown on top of a certain technology platform. The most popular systems included Java ME, Qualcomm's BREW, and dedicated smartphone operating systems, such as Palm OS, Symbian OS, and Windows Mobile. In early phases, Java emerged as the most open environment for mobile game developers, whereas developing a native Symbian, iPhone, or BREW application involved going through a stricter screening and licensing procedure with the handset manufacturer, distributor, or operator. It was with the introduction of the iPhone with its iOS and App Store (2008) that online digital distribution finally started to open up. In 2017 alone, Apple's App Store and Google's Play Store reported over 175 billion app downloads.

Many mobile games still look like scaled-down versions of established video games and game genres. Mobile casual games are a natural option for developers implementing gaming entertainment that is consumed in short breaks while commuting or otherwise filling in time. Many successful games are specifically designed to make best use of the mobile phone interface, including using a simplified control scheme, and enjoyable and varied gameplay is possible using only one push button (Green 2005). However, research and development for mobile games have gone beyond earlier video games formulas and have aimed at exploiting the unique opportunities provided by mobile devices. Such “truly mobile games” include location-based games or games that otherwise exploit context awareness and thus can be equally termed as mixed reality (MR), hybrid, or pervasive games.

Games created for smartphones have also made innovative use of their integrated cameras, Bluetooth capabilities, and built-in sensors, such as gyroscopes, to facilitate augmented reality (AR) gaming. Always-on mobile data connections in contemporary mobile phones allow interesting multiplayer interactions while roaming city streets. *BotFighters* (2000), by the Swedish company It's Alive!, was one of the earliest commercial location-based multiplayer games, relying on GSM cell locations and SMS messaging. The potentials of GPS tracking were also exploited early by experimental MR games such as Blast Theory's *Can You See Me Now?* series (2001–4) and Newt-games' *MogiMogi* (2004) in Japan. The treasure hunting practice of *geocaching* has also become established as a truly mobile style of play.

The phenomenal success of *Pokémon GO*, published by Niantic in 2016, has transformed the landscape of location-based mobile games, with more AR and MR games to follow in the future.

Modifications. See Game Modifications

Molyneux, Peter (1959–)

Peter Douglas Molyneux is an English game designer and computer programmer. Molyneux holds the rank of Officer

of the Order of the British Empire (OBE) and is an Academy of Interactive Arts & Sciences (AIAS) Hall of Fame inductee. He was awarded the title of Chevalier de l'Orde des Arts et des Lettres in 2007 and received an honorary doctor of science from the University of Southampton in the same year. He is the founder of Bullfrog Productions and Lionhead Studios and is currently the creative director of Microsoft Game Studios.

Peter Molyneux's career began when he ran a business that sold and distributed floppy disks in 1982. Later, in an effort to increase sales, he included software on the disks, composed primarily of video games for the Atari 8-bit family series of home computers and the Commodore 64. The positive response garnered from the included games piqued Molyneux's interest in the gaming industry and prompted him to try his own hand at game design.

His first effort, a business simulation game called *The Entrepreneur* (1984), failed to find an audience and sold only two copies. Confronted with this setback, Molyneux temporarily shied away from game design. He founded a new company called Taurus Impact Systems with his business partner Les Edgar. Taurus was set up to design office database systems. Due to a syntax error, Commodore International mistook Taurus Impact Systems for a more established company called TORUS. From this oversight, Molyneux's company obtained a contract with Commodore to redesign a database system for the Amiga computer. Commodore supplied Molyneux with eight Amiga systems to facilitate the redesign. The database program went on to become a financial success and provided Molyneux and Edgar

with the capital they needed to found their own gaming company, Bullfrog Productions.

Under the management of Molyneux, Bullfrog Productions produced ten games over the course of as many years (1987–97). Molyneux's software credits at Bullfrog include *Fusion* (1987), *Populous* (1989), *Powermonger* (1990), *Populous II: Trials of the Olympian Gods* (1991), *Syndicate* (1993), *Theme Park* (1994), *Magic Carpet* (1994), *High-Octane* (1995), *Genewars* (1996), and *Dungeon Keeper* (1997). *Populous* stands as Bullfrog's most successful title and is regarded as the first computer "god game." In 1994, Molyneux became vice president of Bullfrog's publisher, Electronic Arts (EA), which acquired the studio and a significant share of the company in 1995. Molyneux left Bullfrog Productions in August 1997 to start Lionhead Studios.

Molyneux spent three years and \$6 million dollars of his own money developing Lionhead's first title, *Black & White* (2001), a god game that combined elements of action, strategy, and artificial life. The title received critical praise for its programming ingenuity and game mechanics. Additional titles Molyneux designed at Lionhead Studios include *Fable* (2004), *Fable: The Lost Chapters* (2005), *The Movies* (2005), *Black & White 2* (2005), *The Movies: Stunts & Effects* (2006), *Black & White 2: Battle of the Gods* (2006), and *Fable II* (2008). *Fable* was the first game developed by Big Blue Box, a satellite studio of Lionhead Productions. The game was published by Microsoft and available for the IBM PC, Mac OS X, and the Microsoft Xbox. *Fable's* sequel, *Fable II*, was released exclusively for the Microsoft Xbox 360. Microsoft Game Studios acquired

Lionhead Studios in April 2006. In June 2009, Molyneux was promoted to creative director of Microsoft Game Studios.

In March 2012, Molyneux announced plans to step down from Lionhead and Microsoft to work at 22 Cans, a company started by former Lionhead CTO, Tim Rance. The first title for 22 Can, *Curiosity: What's inside the Cube?*, was released on November 6, 2012. The game was a multiplayer social experiment title created for iOS and Android. Over three million users broke through approximately twenty-seven billion “cubelets” to complete the game. On May 26, 2013, Bryan Henderson removed the final piece of the cube to become the game’s prize recipient.

The titles that followed from 22 Cans faced development problems, with *Godus* (2014) and *Godus Wars* (2016) failing to progress past early access on various platforms. In collaboration with publisher Kongregate, the company developed and released *The Trail* (2017) for iOS and Google Play. In April 2017, Molyneux announced development on a new title, *The Legacy*. As of 2019, it remains in preproduction.

Morality and Ethics

Morality and ethics are closely related and overlapping concepts; the terms are often used interchangeably. However, morality tends to concern itself with standards and conduct, whereas ethics focuses more on systems and processes. Put simply, morality addresses the *content* of right and wrong, whereas ethics addresses the *way* of determining right and wrong. For decades, many theorists and researchers have debated the meaning of morality and ethics in video games. Some argue that video game play is of little moral consequence or influence in the nongaming lives of those who play them, but others contend that video games can and do affect the moral development of players.

Matt McCormick (2002) and Ren Reynolds (2002) suggest that the ethical assessment of video games should stem from the historic questions of moral philosophers:

Aristotle (virtue ethics): What produces virtuous character? Can video games produce virtuous character? Does participation in simulated violence erode players’ moral character or hinder players’ flourishing and fulfillment?

John Stewart Mill (utilitarianism): What causes the most harm or the most good? Do the consequences of video game play produce more harm or more good?

Immanuel Kant (deontology): What is one’s highest duty or moral obligation? Does video game play hinder players from performing those duties and obligations? Can video game play assist players to perform those duties and obligations in some way?

Many educators and psychologists argue that video games too often hinder the moral development and behavior of those who play them. Eugene Provenzo's *Video Kids: Making Sense of Nintendo* (1991) offers the first formal assessment of morality and ethics within video games, specifically Nintendo Entertainment System (NES) video games. Provenzo argues against the alleged neutrality of video game media. He contends that an alarming number of video games sponsor a curriculum of violence and sexism. Provenzo also expresses particular concern about the deterministic influence that video games can have on children. Later, the American Psychological Association (APA) passed a "Resolution on Violence in Video Games and Interactive Media" (2005) condemning the violent, racist, and sexist influence of video games. The APA recommends a strategy of media literacy education, industry self-regulation, and the development of a more accurate content-based rating system.

In particular, the social science research of Craig A. Anderson, Douglas A. Gentile, and Katherine E. Buckley (2007) supports the APA's resolution. Their work links violent video game play with verbal and physical aggression, both in the short and long term. Anderson and his colleagues aspire to limit negative media effects on those who play video games. Later meta-analyses support the conclusion that violent video game play among children and adolescents is positively associated with various forms of aggression (Calvert et al. 2017; Prescott, Sargent, and Hull 2018). However, a more recent long-term study of adult *Grand Theft Auto V* (2013) players indicates an absence of negative effects at the conclusion of two months of gameplay and

again two months after gameplay had ended (Kühn et al. 2019). In summary, Provenzo, Anderson, the APA, and others argue that many video games exert an *immoral* influence on players—particularly children who play video games.

In contrast, other researchers argue that video games can exert a *moral* influence on players. For example, Henry Jenkins proposes that critics take a more moderate view of media effects and the moral influence of video games. He discounts the deterministic perspective that violent video games must exert a negative influence on seemingly passive video game players. Instead, he maintains that violent video games constructively offer adolescents "a fantasy of empowerment" and "a fantasy of transgression, a chance to test the limits of their parent's culture" (Jenkins 2000). In other words, video games provide players with a platform for expressing their feelings and working through their life concerns. Jenkins builds his argument on a humanistic perspective that video game players are free to engage in ethical reflection on the games that they play. He suggests that video game play is an active process in which video game players construct their own meanings.

Similarly, Miguel Sicart (2009) argues that video games contain embedded values with which players may freely interact. To Sicart, video game players are moral beings who bring their own perspectives to bear on gameplay. Thus, he maintains that video games can empower players to develop a deeper capacity for ethical reasoning and reflection skills. Sicart suggests, however, that when video games measure and evaluate the players' ethical choices, the games tend to limit the moral development of those who play

them. He argues that when video games explicitly reward in-game moral behavior, that behavior becomes a strategy to win instead of an expression of ethical reflection. In this light, Sicart defines “ethical gameplay” as “the ludic experience in which regulation, mediation, or goals require from the player moral reflection beyond the calculation of statistics and possibilities” (2013, 24). He is a proponent for the kind of video game design that allows players the freedom to express their own values with authenticity and to shape virtual worlds in that light. In summary, Jenkins and Sicart argue that video games present players with a playful opportunity for ethical reflection and moral expression.

Many theorists and practitioners argue that through careful game design, video games can and do sponsor occasions for ethical reflection and moral thought. For example, Ian Bogost (2007) suggests that video game procedures and rhetoric must present players with moral ambiguities that can elicit ethical reflection. However, Harry J. Brown (2008) contends that most video games inevitably shield their players from difficult ethical dilemmas by situating moral decisions within simplistic categories of good and evil. Mark J. P. Wolf (2003) also suggests that video games will remain unable to achieve ethical and moral depth until they elicit deep emotions and feelings from players. Lars Konzack (2008) calls for open-ended video games within which players can experiment with and explore a variety of ethical processes and moral values. The Values at Play project (Flanagan and Nissenbaum 2014) recommends an intertwined triad of game design components to conscientiously embed social values into video games:

discovery (identification of values), implementation (translation of values into game operations), and verification (assessment of gameplay outcomes).

In 1976, Exidy’s arcade game *Death Race* gave players ninety-nine seconds to run over elusive pedestrians in the style of a demolition derby. Dead pedestrians screamed as they were replaced by tombstones. The monochrome graphics were relatively simple. The game described the pedestrians as “gremlins.” Nevertheless, *Death Race* is remembered as the first video game to arouse public moral outrage.

In the 1980s, video games saw innovations on both ends of the moral spectrum. In 1982 and 1983, Mystique published a trio of self-described “adult video game cartridges” for the Atari VCS 2600. The most notorious of the three is the simplistic *Custer’s Revenge* (1982), in which the player character dodged a hail of battle-field arrows before raping a bound female Native American. In contrast, Origin Systems published the innovative computer role-playing game (RPG) *Ultima IV: Quest of the Avatar* (1985), in which players assumed the role of a hero in search of moral perfection. Along the way, the computer kept track of players’ progress in each of eight virtues. Hayse (2009) argues that the morality system of *Ultima IV* effectively enabled ethical reflection from the player largely due to twin factors: the concealment and opacity of its “moral economy” and its reliance on qualitative player feedback rather than quantitative feedback. Combined, both factors contributed to the construction of a “possibility space” (Bogost 2007) for exploring ethical values.

The 1990s stand out as a decade in which graphic violence in video games

led to industry regulation. For example, Id Software popularized the first-person shooter (FPS) with its *Wolfenstein 3D* (1992), *Doom* (1993), and *Quake* (1996) franchises. In 1992, Midway Games launched its *Mortal Kombat* franchise. The year 1994 heralded the establishment of the Entertainment Software Rating Board (ESRB), a self-regulatory body that establishes general guidelines for labeling video games in terms of violence, profanity, and sexual content. As public concern about video games reached acute levels, the 1990s ended with the Columbine High School shootings in April 1999, which were blamed in part on the violent gameplay of *DOOM*. Some critics contested this link (Jenkins 2000).

More recently, moral ideas and ethical processes have moved closer to the forefront of video game design. The RPG *Deus Ex* (2000) engages players in critical ethical reflection on the moral implications of terrorism. Peter Molyneux's real-time strategy (RTS) game *Black & White* (2001) casts players in the roles of fledgling deities who shape the moral development of worshipful tribes through acts of divine benevolence and tyranny. The year 2001 also saw the release of the third game in the *Grand Theft Auto* series, an RPG in which players explore the relative degrees of morality within urban gang life. In 2002, the Serious Games Initiative began to issue proposals for video games that addressed global, social, and ethical issues. The year 2002 also introduced the FPS *America's Army: Operations*—a strict military simulation that replicates the moral practices and ethical processes of serving in the U.S. Army. The RPG *Star Wars: Knights of the Old Republic* (2003) incorporates the moral contrast between the light side and dark

side of the Force throughout gameplay. *BioShock* (2007), another RPG, confronts players with a narrative series of ethical dilemmas and moral choices that reflect the philosophical framework of Ayn Rand. Other video game series, such as *Assassin's Creed* (2007), *Mass Effect* (2007), *The Witcher* (2007), *Dragon Age* (2009), *Red Dead Redemption* (2010), and *The Walking Dead* (2012), also deploy ethical dilemmas and moral choices in gameplay.

Mortal Kombat

Mortal Kombat is a fighting game developed by Midway Manufacturing. Designed by Ed Boon and John Tobias, it was released in arcades in 1992. *Mortal Kombat* was developed as Midway's response to Capcom's highly successful *Street Fighter II* (1991). Although it brought some changes to the established fighting game mechanics—such as a dedicated "block" button or the ability to "juggle" the helpless opponent in the air with well-timed successive hits—it primarily became famous for its gratuitous, over-the-top violence. Not only would well-placed blows send geysers of blood across the screen, but the game also introduced the concept of "fatalities"—spectacularly gruesome finishing

A screenshot of the original *Mortal Kombat*. (Courtesy of Mark J. P. Wolf)

moves. At the conclusion of the fight, while the weakened opponent swayed in stunned stupor, a special combination of joystick moves and button presses would unleash a character-specific deadly attack. These included the ability to decapitate, incinerate, or electrocute the rival. In addition, *Mortal Kombat* used digitized graphics, which at the time appeared highly realistic, especially compared with the cartoonish style of other contemporary fighting games.

Following the game's success in the arcades, *Mortal Kombat* was ported by Acclaim Entertainment for home consoles, handhelds, and home computers. The home console versions were released on September 13, 1993 ("Mortal Monday"), to the accompaniment of a \$10 million advertising campaign—at the time, the most expensive promotional effort by an independent publisher. Flung into the public eye, the game instantaneously

sparked great controversy. Even as some stores refused to carry the title, sales boomed, and *Mortal Kombat* went on to become the best-selling game of the year.

Different ports of the game replicated the arcade original with varying degrees of faithfulness. Notably, the SEGA versions retained all the violence and gore, although the Genesis and Game Gear editions required the player to enter a cheat code to unlock those features. Nintendo, however, in keeping with its family-friendly policy, refused to allow the game on its systems unless a number of changes were made. Thus, the Super Nintendo Entertainment System (SNES) port replaced blood with gray "sweat" and removed or considerably toned down the fatalities (renamed "finishing moves"). As a result, the game became a significant factor in the battle for market dominance between Nintendo and SEGA, with the uncensored Genesis

version massively outselling the SNES version.

The SEGA CD edition also played a major role in the 1993–94 U.S. Senate hearings on video game violence that led to the formation of the Entertainment Software Rating Board (ESRB) and the creation of the video game rating system. Ironically, the hearings, during which *Mortal Kombat* was held up as one of the prime examples of the game industry marketing mature content to minors, generated much additional publicity for the game, accelerating the already strong sales. As a sardonic commentary on the controversy, *Mortal Kombat II* (1993) supplemented the fatalities with “babalities” (turning the defeated fighter into an infant) and “friendships” (offering the opponent a token of friendship). Interestingly, the SNES version of *Mortal Kombat II* reproduced all the gore present in the arcade original.

The game spawned a number of sequels across all major gaming platforms as well as three action-adventure spin-offs. It was adapted into two feature films, *Mortal Kombat* (Paul W. S. Anderson, 1995) and *Mortal Kombat: Annihilation* (John R. Leonetti, 1997). It also inspired the live-action series *Mortal Kombat: Conquest* (1998–99) and the animated series *Mortal Kombat: Defenders of the Realm* (1996) as well as a novel, several comic books, and a trading card game.

Motion Capture and Motion Control

Also designated as *motion tracking* or, commonly, *mocap*, *motion capture* is the process of capturing and recording movements from a real actor or element and then using the translated data to control a digital model. The movements are recorded or restituted in real time through other digital systems as three-dimensional data. This technique helps give an illusion of life to three-dimensional models or avatars by reproducing natural movement, complete with secondary motions that would be difficult to animate realistically by hand. Motion tracking technology was initially developed in the medical world and by the military in the 1970s. During the 1980s, the field began to be combined with that of computer imagery as the technology’s potential was explored, and in the 1990s, mocap technology was progressively applied in film production.

Since the 2000s, motion capture applications have been used in video games in which three-dimensional graphics are involved, in television shows in which virtual settings include digital characters animated by real actors, in professional

sports for performance analysis, and in the art domain for works that range from experimental dance and theater to digital puppetry. As current video game consoles offer significant processing power, players have come to expect believable character models that accurately reflect their human movements and behaviors. Because of the need to record human movement, actors, stuntmen, and martial artists from the film industry have taken on roles in video games, and when motion capture includes one's face and fingers and records a subject's subtle expressions, it is sometimes referred to as *performance capture*.

Two main categories of mocap systems are used in the entertainment industry: optical or nonoptical, which can either be magnetic, electromechanical, or inertial systems. Optical systems were primarily designed for medical applications (e.g., orthopedics, rehabilitation, traumatology, and, mostly typically, biomechanics) and usually involve four to thirty-two cameras controlled by a computer. Capture subjects wear markers that can either be reflexive (passive) or light emitting (active). Passive markers are usually spherical or circular and are attached to the subject's skin or to a full-body mocap suit made from elastic materials. Cameras in a passive marker system are equipped with light-emitting diodes (LEDs), and the passive markers reflect their light. On the other hand, active markers are themselves LEDs. Some active systems illuminate markers one at a time to avoid any identification problem, whereas others activate markers all at once, modulating the amplitude or frequency to identify markers. Optical mocap systems have accurate data and a high capture rate and allow a large number of markers on

different subjects. Their postprocessing, however, is extensive, as markers can be occluded (resulting in loss of data), and lighting must be carefully controlled during capture sessions.

Electromagnetic motion capture systems are sometimes called *magnetic trackers*. They descend from the sensors placed on a military aircraft pilot's helmet to track the pilot's head position. Magnetic systems are usually smaller than optical mocap systems and are less expensive. Position and orientation are available without postprocessing, and they also have the advantage of allowing feedback through real-time applications. Tracking sensors are prone to interference, however, and their wiring and batteries also limit the subject's movements.

Electromechanical mocap systems, such as exoskeletons and data gloves, are articulated devices that directly measure joint angles on capture subjects. They work in real time and are relatively inexpensive, free of occlusions and electromagnetic interferences, and highly portable. The disadvantages of electromechanical mocap systems are that they restrict capture movements, have fixed sensors or configurations, are breakable, and offer low sampling rates.

When motion tracking is integrated into a cybernetic system that manifests change through feedback and adaptation, some control over that system becomes possible. The capture of finger and hand movement enables computer use, as in the case of the keyboard and mouse. From classic joysticks and control pads to more sophisticated game controller devices, the video game industry has integrated a wide variety of motion control devices into its systems.

In November 2006, Nintendo released the Wii Remote (also known as the Wiimote), a control pad coupled with two built-in infrared detectors and miniature accelerometers. The Wii Remote is a low-cost inertial motion capture solution, considering that this technology usually combines a gyroscope, magnetometer, and accelerometer to measure precise rotational rates. The Wii bundle retail package also included the Nunchuk, which features an accelerometer, a traditional analog stick, and two trigger buttons. The Wii MotionPlus expansion device of June 2009 granted a more accurate capture of complex motion and brought motion rendering closer to real time. These devices, compatible with the Nintendo Wii U, allowed position detection in three-dimensional space when directed at the Sensor Bar, which is, in fact, not a sensor but an infrared LED inductor that allows the controllers to be triangulated. The eighth-generation Nintendo Switch console also uses the Wii Remote and Nunchuk.

Four years after Nintendo's Wii Remote, Sony's PlayStation Move appeared in 2010 and included its own duo of main motion controller and sub-controller. The device offered a set of small buttons similar to the ones found on the PlayStation DualShock control pad, and its main controller suggested a magic wand crowned by a glowing orb. The sphere was an active LED marker that emitted colored light along a spectrum to contrast with its environment and allow position detection by the PlayStation Eye. This camera added a location-tracking feature and some visual recognition capability to a magnetometer, a combination that prevented confusion when the device was pointed away from the TV screen or

when the camera lens was blocked. As with the Wii Remote, the PlayStation Move's inertial motion sensing was also based on accelerometers and Bluetooth information exchange with the console. This controller is still compatible with the Sony PlayStation 4 Camera.

Microsoft joined the trend toward motion control through a controller-free entertainment system consisting of an add-on peripheral for the Microsoft Xbox 360, Microsoft Xbox One, and PC, the Kinect—a product line discontinued between 2015 and 2017. A camera projecting infrared light sensed depth, and its sensors enabled it to see in three dimensions under ambient light conditions, allowing software to perform advanced motion recognition, facial recognition, and voice recognition. The system created a direct interaction between the users and the console through a natural user interface, spoken commands, or presented objects and images, even eliminating the need for a handheld game controller.

MUDs. See **Multiuser Domains**

Multi Emulator Super System. See **MAME**

Multiple Arcade Machine Emulator. See **MAME**

Multiuser Domains (MUDs)

Multiuser domains (MUDs), also known as multiuser dungeons or multiuser dimensions, are online worlds in which multiple users can interact together simultaneously, usually through text (MUDs differ from bulletin board systems (BBSs) because of their real-time nature). Although many MUDs are not games, their structure, which allows multiple-user interaction in real time, were sometimes used to build games, and these games became the starting point for the development of massively multiplayer online role-playing games (MMORPGs).

In 1978, Essex University student Rob Trubshaw wrote the first MUD, *Multi-User Dungeon*, on a DEC PDP-10 main-frame computer. Trubshaw turned the program over to fellow student Richard Bartle, who continued developing it, and in 1980, it became the first online role-playing game (RPG) when Essex University became connected to ARPANET. Other MUDs followed during the 1980s, including AberMUD (1987), TinyMUD (1988), LPMud (1989), and DikuMUD (1990). Many of these had “descendants,” other MUDs that were variations using the same or modified software. A MUD in which object-oriented programming is used is called a MOO (MUD, object

oriented), and other terms playing on the original MUD also appeared, such as MUSH (multiuser shared hallucination) and MUCK (multiuser construction kit). In some MUDs, such as TinyMUD, users could build onto the MUD, adding rooms, although some MUDs only gave advanced users these capabilities.

As MUDs grew in popularity, some were set up as commercial online games. In 1983, Alan E. Klietz ported his game *Milieu* to an IBM XT and renamed it *Scepter of Goth*, making it the first commercial MUD in the United States—and an influence on many other commercial MUDs that followed. The game combined single-player text adventure games with the *Dungeons & Dragons* (1974) tabletop game, resulting in a fantasy-themed text adventure world that up to sixteen simultaneous users could play together. Around the mid-1980s, some MUDs appeared that used graphics, such as *Islands of Kesmai* (1985), which appeared on CompuServe, and Lucasfilm’s *Habitat* (1986). Although mostly text based, *Islands of Kesmai* included a small, scrolling graphical representation of a portion of its game world made from ACSII characters (e.g., brackets ([]) represented a wall, a backslash (/) represented a door, and alphabet letters represented the positions of player characters). *Habitat*’s graphics were larger and pictorial, with avatars that looked like cartoon characters and rooms that cut screen to screen.

With the rise of home computers and more and more players coming online, the demand for online games grew, and after the appearance of large-scale graphical-based online role-playing games (beginning with *Meridian 59* [1995]) that could handle thousands of

players, the majority of online RPG players moved to the increasingly larger worlds offered by MMORPGs. However, despite the popularity of MMORPGs and graphical games in general, an audience for MUDs still remains. As of late 2019, the MUD Connector website listed information on 683 MUDs, many of which can be still played online.

Museum of the Game (MOG)

The Museum of the Game (MOG) is the world's largest educational center that focuses on the art, inventions, science, and history of the video game, game, amusement, and coin-operated machine industries. Its coverage includes video games, pinball, mechanical and electro-mechanical arcade games, slot machines, vending machines, trade stimulators, and all other coin-operated devices.

Based in Pasadena, Los Angeles County, California, the MOG provides content and community services related to these machines and protects, researches, and disseminates related knowledge, educational research, and the interpretation of the same. To that end, over more than three decades, it has assembled one of the world's leading

archives covering the art, entrepreneurs, inventions, and history of the amusement and coin-operated machine industries.

One of the key offerings of the MOG is an extensive and growing physical library. Additionally, more than 120,000 pages of educational, research, and entertainment content are available on its website, including more than 100,000 pages of reference content in Acrobat PDF format and more than 20,000 encyclopedia entries covering coin-operated arcade and amusement machines. Other online offerings include a "Machine of the Moment" and message boards where collectors and fans can ask questions and get answers from experts or buy and sell games, machines, and parts. The website receives millions of page views each month. A video game division of the museum called the Killer List of Videogames (KLOV) has created the authoritative database on coin-operated video games; it includes thousands of entries of game descriptions, machine photos, trivia, technical data, and related information.

One of the MOG's goals is to establish a definitive collection of important mechanical amusement devices, coin-operated machines, and video games for enjoyment and education purposes. The collection currently encompasses approximately one thousand machines and tens of thousands of location photos, catalogs, flyers, and items of related memorabilia. A key focus of this collection is documenting key moments in innovation and the evolution of game design, particularly from the 1880s through the present.

The permanent collection includes the three earliest coin-operated arcade games ever made, the world's first kiddie ride, numerous video game prototypes,

and thousands of photos, flyers, catalogs, and related items of memorabilia. Its holdings include the only complete collection of *Computer Space* (1971) specimens, including the only white unit ever made (a prototype).

The collection's machines and select resources are presented by Penny Arcadia, the MOG's events and exhibitions wing. The Penny Arcadia project was initiated in the spring of 1970 by Jon and Patricia Gresham. These efforts culminated in the grand opening of Penny Arcadia on July 17, 1982, in Pocklington, England, twelve miles east of York. It presented a unique combination of expo, museum, theater, arcade, and magic show. It quickly won a Certificate of Merit award from the British Tourist Authority in its Come to Britain Competition. In 2003, the International Arcade Museum and its director, Greg McLemore, took over the operations of Penny Arcadia and moved the collection to Los Angeles, combining it with the machines he had already assembled there.

The MOG also sponsors the International Arcade Museum Library, Inc. (IAML), a 501c3 nonprofit research library that collects and makes available research material related to the amusement, arcade, coin-operated machine, and video game industries, both from its own collection as well as from other libraries and institutions and the collector community. The IAML's goal and purpose is to acquire, preserve, and present a leading archive of catalogs, flyers, photos, obsolete patents, inventions, media, general history, and artifacts about the amusement, arcade, coin-operated, and video game industries. The library works with both the public at large and other libraries, museums, and educational

institutions to preserve artifacts and knowledge so that this history is better known, understood, and appreciated. It is currently expanding, preserving, and cataloging its holdings as well as presenting them to the public (both online and via a physical library) and working to develop educational programs. A pool of funds is also being developed to support a move to larger facilities to facilitate expanded presentation and research space and to support being open to the public at regularly scheduled hours. Donations to the library are tax deductible. The International Arcade Museum Library is independent of, yet receives some sponsorship and support from, the International Arcade Museum.

Another institution sponsored by the MOG is the Vintage Arcade Preservation Society (VAPS), also known as the Video Arcade Preservation Society, a leading worldwide association and census project dedicated to the preservation of coin-operated games.

In 2002, The International Arcade Museum was formed to bring together the KLOV, Penny Arcadia, and VAPS. Ten years later, the Museum of the Game was formed to add non-coin-operated video games to the mix.

Music

The history of music and video games is also a history of diverse platforms and their technological features, commercial circumstances, and forms of usage. Subsequently, each platform provides specific opportunities, challenges, and requirements when it comes to the use of music as design element in their respective games. Nevertheless, there are some major milestones that had an impact on the use of music in games in general, shaping technological as well as compositional approaches and ideas about game music aesthetics.

HISTORY

It was Tomohiro Nishikado's arcade game *Western Gun/Gun Fight* (1975) that featured a short melodic line for the first time: the death of a player's avatar was accompanied by a monophonic version of Chopin's iconic "Funeral March" melodic line. Also, for other early arcade games, the use of classical music was common, as it was available for free and made employing a composer unnecessary. The music had to be written in code for the machine's programmable sound generator (PSG); therefore, it was usually created by a programmer. First-generation home consoles such as the Magnavox Odyssey (1972) did not have the capabilities for music, whereas second-generation devices such

as the Fairchild Channel F (1976), the RCA Studio II (1977), and the Atari VCS (or Atari 2600, 1977) with its Stella/TIA chip could produce sounds and monophonic melodies. Nevertheless, it is Taito's arcade title *Space Invaders* (1978), also created by Nishikado, that is credited for being the first game featuring a continuous soundtrack that changes with gameplay, thereby paving the way for the idea of what became known as dynamic, reactive, adaptive, or interactive music. Two years later, the first game accompanied by a continuous polyphonic loop, the arcade maze racing title *Rally-X* (1980), was released.

During the early and mid-1980s, the introduction of FM synthesis, made possible by Yamaha's sound chips and FM synth boards that were built in Japanese arcade machines and home computers, allowed for more complex chiptune compositions. At the same time, the 8-bit tunes of Nintendo Entertainment System (NES)/Famicom games and game series such as *Dragon Warrior/Dragon Quest* (Koichi Sugiyama), *Super Mario Bros.* (Koji Kondo) and *Final Fantasy* (Nobuo Uematsu) set standards for what players came to associate with game music on consoles, especially in the Western Hemisphere. Besides the quality of the music and the ways it was used as a design element in the games, as well as the creative use of the consoles' sound capabilities, the dominant market position of Nintendo at that time may also have played a part.

Meanwhile, in the realm of home computers, machines such as the Apple II; the Sinclair ZX Spectrum; the Commodore 64, with its famous Sound Interface Device (SID); and the Amiga series became affordable for private users and

gathered their own fan bases because of their distinct sound aesthetics. Composers such as Rob Hubbard (e.g., *Monty on the Run* [1985]), Martin Galway (e.g., *Daley Thompson's Decathlon* [1984]), and Chris Hülsbeck (e.g., *The Great Giana Sisters* [1987]) used not only their musical but also their masterly programming skills to coax seemingly impossible sounds out of the given hardware. Thanks to home computers being open and programmable systems, players at the same time started to create their own games or hacked the copy protection of commercial titles. Cracked games were marked with an intro, a short program that started before the game, and oftentimes contained computer music. From this practice, both the demoscene and the musical genre of chiptunes, outside of the games themselves, emerged. Although commercial music programs such as the Commodore Music Maker (1982) were released, they were hard to handle and too inefficient for creating games or demos; therefore, the community started to develop their own tools. In 1986, Chris Hülsbeck released his *Soundmonitor* program as a type-in listing in the German computer magazine *64er*, making music creation on the Commodore 64 much easier.

Another beloved instrument of chiptune musicians, due to its distinct sound, was the Nintendo Game Boy, released in 1989. With this device, polyphonic melodies came to handheld gaming. Earlier LED and LCD handheld electronic games, released by companies such as Mattel Electronics (e.g., *Auto Race* [1976], the first all-electronic handheld video game), Milton Bradley (e.g., *Microvision* [1979], the first handheld system using interchangeable cartridges), and Nintendo (e.g., their Game & Watch series [1980–91]), had

produced sounds and sometimes very brief monophonic melodic lines using piezo-electric speaker beepers.

During the mid-1980s and early 1990s, the capacities of 16-bit home computers and consoles, the wider adoption of FM synthesis, and the introduction of MIDI (Musical Instrument Digital Interface protocol) allowed for new approaches and sound aesthetics. Though General MIDI (which was already introduced in 1982) was limited to 128 instruments, it became possible for composers to create music without having to handle programming languages themselves or rely on a programmer. However, the final sound of the music now strongly depended on hardware playback devices, which was not a problem on consoles, with their standard features. On a home computer, though, composers could never be sure how their creations would sound. Nevertheless, MIDI also allowed for new approaches in terms of flexible implementation. A major milestone was the iMuse (Interactive Music Streaming Engine) that Michael Z. Land and Peter Connelly had created and used in LucasArts' point-and-click-Adventure *Monkey Island 2: LeChuck's Revenge* (1991). It included two crucial innovations. First, iMuse allowed for the flexible use of musical transitions between two pieces of music to produce a seemingly continuous soundtrack. Second, iMuse could create small variations in the music mix to give the impression that the music responded to the player's actions. These two basic principles became known as horizontal resequencing and vertical reorchestration. In terms of sound aesthetics, it was mainly SEGA and its 16-bit console, SEGA Genesis/SEGA Mega Drive, that took advantage of the new

possibilities. As the machine's Yamaha YM2612 sound chip could mimic typical progressive rock keyboard sounds, composers created driving soundtracks in that very style. In 1986, the SEGA arcade racing game *Out Run* entered game music history by being the first arcade game that allowed users to choose the soundtrack (the composer was Hiroshi Kawaguchi). The game's music later became a major inspiration for the mid-2000s electronic music genre known as Synthwave, Outrun, or Retrowave.

The Panasonic 3DO Interactive Multiplayer console, which hit the market in 1993 but flopped due to its high price of \$699, was the platform for which Sid Meier and Jeff Briggs released their notable music-generating program *C.P.U. Bach* (1993). Based on the user's input, it generated Bach-styled pieces for various instruments. It was Sony's PlayStation (1995) with its CD-ROM drive that became the next game changer in terms of music. Besides MIDI, the console allowed for Red Book Audio in CD quality. While having several advantages (such as better sound quality), Red Book Audio also came with several downsides, most notably a setback in terms of flexibility; hard cuts between tracks and rapid fades were among the consequences. Nevertheless, composers could now make use of vocals and all instruments. In 1996, Sakura Taisen already featured some orchestral parts, and both *The Lost World* (1997) as well as *Heart of Darkness* (1998) featured a full orchestral score. While the soundtrack for the latter had been recorded earlier, the game's release was delayed so that it was published after the former.

The PlayStation also became a playground for music game designers. In

1996, Masaya Matsuura's rapping game *PaRappa the Rapper* helped start the music game genre in Japan. With Jaron Lanier's *Moon dust* (Commodore 64, 1983), Toshio Iwai's *Otocky* (Famicom, 1987; never released outside Japan), and Lucasfilm Games' *Loom* (1990), music game predecessors made creative use of a digital games' specific opportunities for involving the player in music creation. But it was *PaRappa* that started the music game boom, together with Konami's arcade music game *Beatmania* (1997). The smashing success of *Beatmania* institutionalized Konami's music game division, Bemani, which produced hit arcade music games and series, including the *Beatmania* series, the *Guitar Freaks* series, and the *Dance Dance Revolution* series. *Dance Dance Revolution (DDR)* (1998) was also released in 1999 in North America and in Europe (under the name *Dancing Stage*) and spawned a vital player community.

Despite *DDR*'s success, the genre of music games sustainably hit the Western Hemisphere in the form of *Guitar Hero* (2005) for the PlayStation 2. The game was inspired and strongly influenced by its Japanese predecessors in terms of design. Besides its outstanding commercial success, *Guitar Hero* was celebrated, and at the same time infamous, for its influence on the music market and relations with the music industry. Whereas some musicians and groups came to light thanks to their songs being licensed for the game, others went through their second commercial springtime due to a dedicated *Guitar Hero* title (e.g., Metallica and Aerosmith), and still others declined a deal (e.g., Led Zeppelin), as they felt it to be a sellout of their music; they called on players to pick up a real guitar instead.

Such interrelationships and cross-marketing approaches were nothing new by this time; bands had been involved since *Journey Escape* (1982) for Atari VCS was released.

Throughout video game history, stars with backgrounds in all kinds of musical genres have been involved with video games, composing the music for games or even appearing in games as a character or as themselves, including Michael Jackson (several SEGA games, such as *Michael Jackson's Moonwalker* [1990] and *Space Channel 5* [1999]); David Bowie (*Omikron: The Nomad Soul*, [1999]); 50 Cent, Dr. Dre, and Eminem (*50 Cent: Bulletproof* [2005]); Phil Collins (*Grand Theft Auto: Vice City Stories* [2005]); Brian Eno (*Spore* [2008]); and Ozzy Osbourne, Lemmy Kilmister, Lita Ford, and Rob Halford (*Brütal Legend* [2009]).

Today, technology allows for all kinds of musical styles, aesthetics, and genres. Nevertheless, there are constraints to available options and a composer's creative freedom. These include a game's genre and the subsequent player expectations for a suitable soundtrack, the available budget, the ideas and specifications given by publishers or developers, and time constraints or the circumstances of involvement in a game project. With few exceptions (such as Konami's Bemani division), composers are usually not permanently employed at game companies; instead, work for hire is common. This practice, plus sometimes restrictive non-disclosure agreement clauses, has consequences for the creative process. Some composers report getting only some artwork from, and minimal information on, the game for which they are composing as well as vague directions as to what kind of music is expected. Optimally,

composers should be brought into a project at an early stage; be given enough information to tailor the soundtrack precisely to the game, its gameplay, and game feel; and be involved in implementing the soundtrack into the game, as these are, besides compositional quality, other key elements in creating an overall satisfying gameplay experience for the player.

PRODUCTION

Game music is oftentimes compared to film music. There are, indeed, similarities in the way music is used as a design element to meet certain audience expectations (what kind of music fits a specific scene or event), which are oftentimes established by other media, such as film or television. For this reason, techniques deriving from the field of film scoring are also used in games. Common approaches are Mickey Mousing (synching the music with the actions on screen), underscoring (background music that helps to establish the mood of a scene), mood technique (music that reflects or reveals the feelings of a character on screen), or the use of leitmotifs (derived from opera, establishing a motif as the musical representation of a character, relationship, narrative thread, etc.).

A major difference between a game and a film score is that a game soundtrack must allow for flexible implementation. Whereas a film presents an unchangeable sequence of events for which a film composer creates a score, a game composer cannot foresee what a player will do at what point. Additionally, a player's reactions can rely on musical cues or motifs; besides a merely narrative function, music in games can deliver gameplay-relevant

information, aiding the player's decision as to what to do or not do. In any case, the music has to fit whatever event will be the consequence. To achieve this goal, technological solutions as well as specific compositional strategies have emerged, such as branching, layering, using a transition matrix, parallel composing, or using forms of procedural audio.

Branching means that a piece of music is split into different layers. If a certain event happens, individual layers can be muted or replaced by another version. These changes are determined by so-called cues or custom markers. Likewise, the nature of the transition must be defined. A similar technique is *layering*, but only one layer is added or muted, for example, a single instrument. When using branching or layering, the composer must make sure that all layers sound good with the rest of the music and sound effects at any time. Another method is the *transition matrix*: The composer writes several short pieces of music and a series of transitions; it must be possible to jump, in a musically meaningful way, from any piece to any other piece of music by using the appropriate transition pieces. Transitions can take place at different points (e.g., immediately, at the end of a phrase, or with a set custom marker) as well as in various ways (e.g., crossfade, fade in and fade out). *Parallel composing* means writing a longer piece of music as well as other tracks with the same basic musical parameters (e.g., key, tempo) but in a different mood. During play, one track is replayed, and the others are muted until a defined game event triggers a switch to another track. The goal is to allow the seamless interchange between these tracks at certain points without using additional transitions.

This means that during the compositional process, any change in a track must be traced in all parallel tracks. Another option involves forms of procedural audio created, for example, by using Markov chains. The music is then generated in real time by the computer on the basis of predefined rules.

Besides hiring a composer to create an original soundtrack, other ways to include music in a game are licensing existing music or using free tracks from music libraries.

RECEPTION AND CULTURE

Since the late 1970s, game tunes have not just been heard during gameplay; instead, the sounds and music were reused within diverse cultural artifacts and practices, appearing in other media forms and musical genres.

In 1979, the single release “Computer Game/Firecracker,” from the album *Yellow Magic Orchestra* by the eponymous Japanese computer music group, started with arcade game music from titles such as *Gun Fight* (1975). The song became a major hit, selling four hundred thousand copies in the United States alone and had a major influence on emerging musical genres such as hip-hop, electro, and early techno. The first pop title that included original game music was “Space Invaders” by the Australian group Player One, also in 1979. In December 1981, the single release “Pac-Man Fever,” from the eponymous concept album (1982) by Buckner & Garcia, was released and sold more than one billion units in the United States alone.

Furthermore, games and their music were also present in TV shows, commercials, and 1980s movies of all types, such

as *Tron* (1982), *Koyaanisqatsi* (1983), *War Games* (1983), *The Karate Kid* (1984), and *The Last Starfighter* (1984). In TV commercials, especially high-grossing hit titles such as *Pac-Man* (1980) or *Super Mario Bros.* (1985) were used to either advertise branded products such as the Nintendo Cereal System or thematically matching items such as food or soft drinks. In 1989, *The Super Mario Bros. Super Show!* aired on TV, featuring Lou Albano as Mario and Danny Wells as Luigi. It was a mix of live-action segments plus *Super Mario* and *The Legend of Zelda* cartoons. Its theme song (“The Plumber Rap”) and the outro (“Do the Mario”) were rap versions of the famous *Overworld* theme, including several sound effects from the game.

Though never completely out of the picture, especially since the mid-2000s, retro game aesthetics have resurfaced in broader pop culture, for example, in the aforementioned Synthwave music genre. More and more musicians started to use and reuse sounds and music from early games in their songs or albums or create music drawing on 8-bit and 16-bit sound aesthetics. Additionally, entire gaming-themed movies, such as *Scott Pilgrim v. the World* (2010), *Wreck-It Ralph* (2012), and *Pixels* (2015), feature the typical “golden era” 8-bit aesthetics and associated sound.

In Japan, game music had occupied a far more important place by the 1980s. In 1984, the first album was released by Alfa Records. It contained the original music of successful Namco arcade titles such as *Galaga* (1981), *Dig Dug* (1982), and *Xevious* (1982). The producer was Haruomi Hosono, a member of Yellow Magic Orchestra. Due to the album’s huge success, a second album featuring music

from *Super Xevious* (1984) was released the same year. By 1986, the heyday of Nintendo’s Famicom, twenty-seven game music albums had been published. The same year, Obi Kazusuke, a former producer of Yellow Magic Orchestra, founded the first label exclusively dedicated to game music and chiptunes, G.M.O. Records, which was an imprint of Alfa Records. Subsequently, the number of game music releases increased significantly. Additionally, magazines such as *Beep* and *Gamest* covered the topic of game music, offering instructions on how to record arcade music on-site and promoting so-called SoundTeams, such as Taito’s Zuntata or SEGA’s S.M.T. Team, who performed their music live, including at the first Game Music Festival in 1990. The magazines further included sheet music or sometimes even flexidisks (sonosheets) that contained game tunes and could be played on phonographs.

In 1987, the first orchestral live performance of game music took place in Suntory Hall in Tokyo. Conducted by composer Koichi Sugiyama, “*Dragon Quest I* Symphonic Suite” and “*Dragon Quest II* Symphonic Suite” were performed by the Tokyo Strings Ensemble alongside Camille Saint-Saëns “*Le Carnaval des Animaux*.” The concert recording was released the same year. The first commercial game music concert outside Japan took place sixteen years later, in the Gewandhaus, Leipzig. Produced by Thomas Böcker, the “*Erstes Symphonisches Spielemusikkonzert*” was part of the official opening ceremony of the Games Convention trade fair. Since then, orchestral game music performances have taken place all over the world, as special performances by a standing orchestra, in the form of

dedicated tour productions or as anniversary concerts.

Beyond orchestral concerts, fans perform game music using all kinds of instruments and materials, creating their own tributes, game filk songs, and mash-up videos. Video platforms such as YouTube and Nico Douga contain uncountable videos of such cultural fan activities.

All these phenomena and their history have become the subject of the developing academic field of ludomusicology, the study of video game music in games and related contexts.

RESEARCH

The neologism *ludomusicology*, coined by Guillaume Laroche in 2007, is composed of the words *ludology* and *musicology*. First, ludomusicological research deals with the history, aesthetics, and practice of music as a design element in games; the specific genre of music games; cultural effects such as fan culture and its social practices; the development of a distinct orchestral performance culture; and the further processing and interaction with other media forms or musical genres. Second, ludomusicology aims to expand the perspective of musicology: beyond the hitherto predominant text paradigm, which places emphasis on score analysis, music is understood and analyzed as a playful practice. Third, there are also musical-pedagogical considerations, for example, to what extent (music) games and various forms of playful approaches can promote the learning of musical skills. All these topics are approached from multiple perspectives that focus on the technological, cultural, aesthetical, or compositional developments of diverse

game genres. Additionally, overarching theoretical approaches and a suitable terminology for analysis are developed and discussed.

Following some early articles and books, the number of anthologies and monographs dealing with the specific subject of game music has been steadily increasing since 2012. Furthermore, since the foundation of the first Ludomusicology Research Group in 2011, ludomusicologists have started to organize conferences, build subgroups within musicological societies, and engage in lively international and interdisciplinary exchange. In 2016, the international Society for the Study of Sound and Music in Games was established as a head organization.

As the field is relatively new and as most researchers are by now located in English-speaking countries, such as the United States, the United Kingdom, and Australia, as well as in Europe, game music history usually mainly focuses on games from North America, Europe, and Japan. Unearthing and documenting other game music histories and looking more closely at diverse national developments are among the major tasks that still need to be undertaken by ludomusicological researchers.

Myst

Cyan's *Myst* (1993), a point-and-click adventure game, held the title of best-selling video game of all time from 1993 until 2001, when it was passed up by *The*

Sims (2000). *Myst* was not only responsible for a flood of imitations in the years that followed its release, but it was also the game that inspired the sales of computers with CD-ROM drives and promoted the advance of CD-ROM-based games in general. *Myst* raised the bar for graphics (considered photo-realistic at the time), world-building, deep space staging, location-based ambience, and immersive gameplay and was a crossover game appealing to men and women and audiences of all ages.

Myst's world was made up of more than twenty-five hundred screens of pre-rendered three-dimensional graphics, representing the views of Myst Island and several Ages, or lands, that players traveled to through the use of linking books, which acted as portals from one location to another. With an unhurried, contemplative pace, players began on Myst Island with no objective other than exploration and learning how various machines worked. As players connected clues, they gained access to new locations, where details would further reveal information pertaining to the storyline embedded in the game. The locations also contained red and blue pages that could be collected and deposited in the Myst Island library, where two characters, Sirrus and Achenar, addressed the player from books, revealing more information about their situation and that of Atrus, their father. In the end, having collected information and pieced together the story of what had happened, players were faced with making a final decision that would determine which one of four endings would occur. Many of the puzzles in *Myst* were environmental in nature, requiring an understanding of the game world's geography, with actions that sometimes

had consequences for another area of the game. *Myst* was designed to take about forty hours of gameplay to be solved.

Myst's success was followed by three novels, a board game, and a series of sequels, including *Riven* (1997), *Myst III: Exile* (2001), *Uru: Ages beyond Myst* (2003), *Myst IV: Revelation* (2004), and *Myst V: End of Ages* (2005). *Myst* would twice undergo revision and rerelease, appearing with enhanced graphics and sound and a “DigitalGuide” hints feature, as *Myst Masterpiece Edition* (1999) and *realMYST* (2000), which rendered its three-dimensional graphics in real time as the player's point of view moved smoothly through its spaces and for which new models of everything were generated using the original *Myst* models

for reference. Finally, *Myst* was rereleased again as part of the *Myst 10th Anniversary DVD Edition* (2003), and versions were released for iOS, Android, Nintendo DS, PlayStation Portable (PSP), and other systems.

Today, *Myst* remains an influential game both in the adventure game genre and in the history of video games in general, showing that games need not be fast paced or violent to be successful.

N

Namco

In 1955, Masaya Nakamura set up the Nakamura Manufacturing Company to operate and maintain two secondhand coin-operated mechanical horse rides for children in the roof garden of a department store in Tokyo, Japan (Kent 2001, 74). The company, the name of which was shortened to Namco, grew in the next two decades and manufactured and operated its own coin-operated amusement rides (Kohler 2004, 15). Its foray into the video game industry began when Atari started shipping *PONG* (1972) machines outside of the United States in 1973. Atari opened up a Japanese branch to oversee importation and distribution of its arcade games, and Namco was among its Japanese clients. Because of market difficulties, the independently operated Atari branch was sold off to Nakamura in 1974, and Namco became Atari's chief distributor in Japan.

Atari's first major hit in Japan came in 1976 when Namco began distributing *Breakout* (1976). The wildly successful game became the subject of a counterfeiting ring operated by the Yakuza. A disagreement between Nakamura and Atari's Nolan Bushnell on how to respond to the illegal machines resulted in Namco terminating its relationship with Atari to go into business for itself (Kohler 2004, 77).

In 1979, Namco employee Toru Iwatani set out to make a nonviolent game centered around eating. Drawing his lead

character from a pizza with a slice removed and his enemies from cute ghosts designed to appeal to women, Iwatani and his nine-man team created a game about eating dots in a maze. Soon, *Pac-Man* (1980) became Namco's first global success and marked the company as forerunners in the burgeoning arcade game industry. Other notable Namco games of the golden age include *Galaga* (1981), *Dig Dug* (1982), *Xevious* (1982), and *Pole Position* (1982).

Although the company changed ownership and subsidiaries numerous times over the three decades following *Pac-Man*, the Namco name remained a fixture of the industry. Namco continued to make arcade games throughout the 1980s and ported its most successful games to home consoles. In the 1990s, Namco reclaimed its spot in the popular imagination by bringing its games to the Sony PlayStation; the arcade hit *Ridge Racer* (1993) was one of the most popular early PlayStation games. The continued popularity of arcades in Japan led Namco to continue designing arcade games into the 2000s and the establishment of series such as *Soulcalibur*, *Tekken*, and *Time Crisis*, which have spawned numerous sequels. Other popular Namco game series include the quirky ball-rolling *Katamari* games, the fifteen-plus titles in the *Tales* role-playing game (RPG) series, games based on popular anime, and the *Dark Souls* series of games.

In 2005, Japanese toy company Bandai acquired and merged with Namco,

forming a new parent corporation Bandai Namco Holdings Inc. The company continues to publish games for home consoles, computers, and mobile devices as Namco Bandai Entertainment, while the arcade and redemption game division operates under the name Bandai Namco Amusement Inc.

Narrative

Narrative theory grew to prominence with the rise of structuralism in the early 1960s, under inspiration from Russian formalists such as Vladímir Propp. In the traditional description, a *narrative* is the structured presentation of a *story* (a fixed sequence of events) by way of a *discourse* (Chatman 1978). It is common for narratives to present their story events in nonchronological order, and reading a novel or watching a movie generally involves reconstructing a story on the basis of the discourse presented.

In terms of *content*, narratives tend to deal with the experiences of human or anthropomorphic entities that have

emotions and beliefs (Fludernik 1996). The content of a narrative is usually governed by a principle of coherence and economy in which events follow causally from each other, and we expect the narrator to mainly communicate information that is relevant to the development of the story. Some contemporary writers use narrative in a very broad sense (Bhabha 1990) or claim that narrative structures underlie all human thought (Schank and Abelson 1977), but for the purpose of studying video games, considering narrative in a narrow sense is more productive because it yields more precise critical tools.

The relationship between video games and narrative has been the subject of continued debate in video game studies. The two extreme viewpoints on the issue are commonly referred to as the *narratological* argument that games are (or should be) narratives and the *ludological* argument that games are fundamentally distinct from narratives. On the far end of the narrative side of the spectrum, Janet Murray suggests that computers and gamelike structures are a new medium for storytelling (Murray 1998, 11). At the other end of the spectrum, Markku Eskelinen claims that any association of video games with narratives is fundamentally flawed because people generally have no difficulty distinguishing between narrative and gaming situations (Eskelinen 2004, 36).

There is a risk that such a discussion becomes too general to be useful, but from the distinction between discourse and story, it follows that the role of narrative in games can be examined in more detail from either the perspective of game structure or from the perspective of game content.

GAME STRUCTURE AND NARRATIVE STRUCTURE

In the traditional sense of the term, a narrative presents a series of fixed events. This makes it straightforward to pose the fundamental argument that because games by definition must have variable outcomes, they are always nonfixed series of events and therefore fundamentally nonnarrative (Juul 2001). The simplest way of dealing with this contradiction in game design has been to develop branching narratives as found in the *Choose Your Own Adventure* book series (Packard and Montgomery 1979–present). From a theoretical point of view, this approach requires that we extend our concept of narrative to include some element of openness and nonlinearity, which raises the question of whether a branching narrative can maintain the coherence and economy of a linear narrative. From a practical point of view, it also threatens the developer with a combinatorial explosion of branching points to give players agency.

Although some modern video games contain branching narratives, video game history has led to the development of two central methods through which games can retain their interactivity while still presenting a series of predetermined events. First, many single-player video games let the player complete a predefined sequence of challenges. Within the individual challenge, the player is given some amount of freedom, but by completing the game, the player will traverse an overarching predetermined sequence of events. This is the most common method for representing a linear narrative in game form. Second, *environmental storytelling* allows a game to

present narrative content by infusing story elements into the physical space of a game or alongside the actions of the players (Carson 2004).

GAME CONTENT AND NARRATIVE CONTENT

In game design literature, Chris Crawford has made the complementary argument that current video games present players with a very restricted number of *verbs* (such as “run,” “jump,” etc.), whereas the protagonist of a proper story has access to thousands of verbs dealing with social interaction, human communication, and so on (Crawford 2003, 165–167). Crawford implores designers to expand the range of actions available to players, but this presents several technical and design obstacles, the main one being that although it is straightforward to implement spatial movement in game rules and computer programming, it is extremely difficult to implement social interaction and especially human language using the same tools. There are five common ways of working around the difficulty of placing story content in games.

First, the traditional method for dealing with the difficulty of implementing human interaction has been to not implement human interaction at all, but rather to represent it in nonplayable cutscenes. Second, *The Sims* (2000) avoids the problem of human language by having characters speak the nonsensical language of “Simlish,” thereby leaving it to players to imagine what is being said in the game. *The Sims* is not a narrative in terms of structure, but its content (the emotional state of characters) is quite similar to the content of many narratives and is easily

retold by players. Third, some of the design issues and technical problems of creating character interaction can be circumvented by using settings that limit the player's expectation toward what characters could or should do, such as dealing with a couple's marital problems in *Façade* (Mateas and Stern 2005). Fourth, recent games, such as *Dear Esther* (2012), more radically only let players walk, and they reward walking with voiceover narration of the game's central story. Fifth, smaller experimental text-based games made with the Twine tool, such as *Howling Dogs* (2012), solve the problem by highlighting it, foregrounding the game's artificial structure, and inviting players to actively engage with the artificialities of game-based narration.

There are substantial barriers to creating games with the typical story content of human behavior and interaction that we expect from traditional narratives. These barriers, however, specifically concern single-player games; multiplayer games are an entirely different matter. By involving humans as players, multiplayer games avoid the problem of implementing human interaction entirely; from a structural point of view, multiplayer games are rarely narratives, but because such games feature humans in the first place, it is easy for players to tell a story *about* a game session. Like in the previous example of *The Sims*, this shows the importance of distinguishing between narrative structure and narrative content.

VIDEO GAMES AND NARRATIVES

The caveat of using narrative theory to examine video games is that it was developed for purposes other than studying video games and therefore does not say

anything about video games specifically. Narrative theory can nevertheless be used with caution by identifying what the theory does not explain to see what is unique about video games.

In abstract games, gameplay can provide a type of interest that is independent of narrative; at the same time, the fiction of most contemporary video games helps players understand the affordances of the underlying rule system. For example, players tend to assume that an object that looks like a car can be used for driving (Juul 2005, ch. 5). Finally, games have a unique capacity for building an emotional connection to game events and characters by sharing a journey over the course of a game, such as in Jason Rohrer's *Passage* (2007) and *Ico* (2001), or by giving players a sense of *complicity* in unpleasant events, as in Brenda Brathwaite's board game *Train* (2009).

The discussion of whether video games are narrative was foundational for the field of video game studies. Although the debate occasionally reemerges both in academia and in the game industry, the question is no longer one of yes or no, but one that asks which components of traditional narratives work well in video games and which work less well, how games deal with the import of material from other media, and what video games can and cannot do.

Navigation (Spatial)

The graphical nature of video games combined with the tendency toward representational graphics has resulted in the concept of video game spaces that are

like miniature worlds. Many games have spaces so elaborate that spatial navigation becomes an important part of gameplay. Navigation is an interaction with space itself, a space through which one actively makes choices to find one’s way around. Navigation involves freedom of movement and connected spaces, the connections of which are explored and learned through navigation.

To discuss spatial navigation, we can consider spaces as being made up of spatial cells, each of which is a continuous, Euclidean space that allows noncontingent two-way movement between all possible positions within that space, all of which is contained within boundaries (which may include a barrier regulating movement into and out of the space, such as a wall or doorway; a line of demarcation, such as the line between two countries on a map or between squares on a chessboard; or a technical limitation, such as a screen edge or a cut to another screen). Boundaries divide up the space of a game’s world for the purposes of programming it: to separate locations and events; to help players to better conceptualize the game’s spaces; and to give a sense of progress and accomplishment as the player moves through, conquers, or completes parts of the game. Such breaks also allow a player to rest between levels, view cutscenes, save games, and so on.

Spatial cells are connected together in configurations that make up a game’s world. Connections between spatial cells can be navigable, visible, both, or neither. Navigable connections allow the player character to *travel* from one spatial cell into another, whereas visible connections allow players to *look* from one space into another; some connections, such as windows or locked doors, may

allow a player to look into a space without being able to move into it. Likewise, the navigability and visibility of connections can be turned on and off as connections are opened and closed or locked and unlocked. Movement and visibility between two spaces can also be two-way connections, allowing access in both directions, or one-way, in which access is available in one direction but not the other (e.g., one-way mirrors or surveillance monitors that show another space). Connections between spaces can also be implied, without being navigable or visible, such as spaces shown on a map of the game's world.

Connections between spaces can also be contingent (based on a game's state) or noncontingent (always the same, regardless of game state). Connections may also be hidden and only revealed at a later point in the game, when an object, place, or avatar is in a certain state—for example, if a character has a key, if the lights are on, if secret passageways are open (as in the library in *Myst* [1993]), or if a vehicle is summoned (as in *Riven* [1997]). Such connections are not contingent if they always connect to the same place; only those that change their connectivity (what they connect to) based on various game states can be said to be contingent (e.g., an elevator that opens out onto different floors, depending on the position of the elevator, or the user-created portals in *Portal* [2007]). Mapping out all the connections between a game's spaces can be difficult because of hidden and contingent connections and spatial configurations that change over time during gameplay in which connections appear and disappear.

Spatial navigation often relies on the experiences involved in navigating

physical spaces, making navigation intuitive and logical. However, spaces may be connected to themselves or to other spaces in such a way that they result in non-Euclidean structures that are physically impossible. Due to their nonintuitive nature, such spaces can complicate navigation, and games that use them often position spatial exploration as an important part of gameplay. Even single spatial cells can be connected to themselves in such a way as to become non-Euclidean; for example, the wraparound screen used in *Asteroids* (1979) forms the surface of a 2-torus—a surface with curves that violates Euclidean consistency. Spatial cells that are themselves Euclidean in nature can also be combined in ways that make the resulting overall structures non-Euclidean, such as the game world of *Adventure* (1979). Connections between spatial cells, however, are not Euclidean or non-Euclidean in and of themselves; only the structures that result from them are Euclidean or non-Euclidean.

In some games, spaces are experienced linearly, resulting in long, gradually revealed, track-like spatial cells, as in many racing games and rail-based shooting games. These spaces may require *steering*, which differs from *navigation* in that the player is merely avoiding obstacles, shooting targets, or keeping to a course or route, whereas the overall direction of movement requires no way-finding or decision making. Such track-like spaces can themselves be spatial cells that are connected into larger structures. It is also possible to have spatial cells with boundaries that are constantly changing, which means the cells themselves could be growing and shrinking and even coming into existence and going

out of existence. In such games, players would have to continually relearn spaces to navigate them; in such cases, only navigation logic may help the player make sense of a game's spaces.

Navigational logic consists of three distinct things players must learn: what spaces exist, how spaces are interconnected (through the learning of boundaries and obstacles), and how interconnections work. In games in which spaces and their connections are changing, the process can be complicated, and a game may be designed to deliberately reject navigational logic, leaving no consistency on which a player can rely. Spatial navigation can also be made difficult by lack of a map, enemy characters who passively block connections or actively attack the player, obstacles that block movement or visibility, lack of time to complete navigational tasks, and narrative sequences that interrupt exploration. Regardless of the degree to which a game employs navigational logic, navigable space remains an important part of gameplay and an essential skill needed by video game players.

Navigation (Temporal)

Although most video games involve aspects of spatial navigation, some also emphasize temporal navigation; in these cases, players must actively control time or maneuver through temporal structures within a game. Games may emphasize temporal navigation as a core game mechanic or merely a feature of play. They may permit players to perform a range of actions, such as slowing time's passage within the game's diegetic world or reversing time to undo mistakes made during gameplay. This ability to alter time is often incorporated into the game's narrative, characterizing the temporal control as a "special power" of the player's avatar or linking it to an object found by the player.

Spatial navigation is a central element of many video games because players must typically maneuver avatars through a game space (as in *Super Mario Bros.* [1985]) or manipulate game elements to achieve predefined results (such as directing the descent of tetrominoes in *Tetris* [1985]). Temporal navigation games often require similar aspects of spatial movement and place an emphasis on traversals and modifications of game temporality. Perhaps the most common adjustments and manipulations of time within a game occur when the player slows time to better navigate the game space in response to enemies and other challenges. The gameplay of Remedy Entertainment's *Max Payne* (2001) employs a feature called "bullet time" that allows the player to selectively slow the movement of time (and thus the movements of enemies) within the game, allowing the player to maneuver more easily and defeat enemies during gun battles. Providing the player

with the ability to slow time is not limited to specific games; software “cheats” may allow such functionality. In a similar vein, Nintendo released the NES Advantage joystick in 1987 for the Nintendo Entertainment System (NES), which featured a “slow” button that slowed many NES games through a pause mechanism by repeatedly suspending and resuming games.

Games may allow (and even require) players to maneuver through the temporal structure of the diegetic game world to accomplish specified tasks. Nintendo’s *The Legend of Zelda: The Ocarina of Time* (1998) provides players with a musical instrument that permits them to play a number of musical tunes, some of which specifically allow for temporal movement. One song allows the player to switch the game world back and forth between day and night, and another permits the player’s avatar to swap between childhood and adulthood (with the game worlds for each being distinct but intertwined spaces). This diegetic temporal exploration is furthered in the sequel, *The Legend of Zelda: Majora’s Mask* (2000), and can be found in earlier games, such as Jordan Mechner’s *The Last Express* (1997) and Roberta Williams’s *The Colonel’s Bequest: A Laura Bow Mystery* (1989).

Other games incorporate temporal navigation as a core game mechanic, requiring the player to actively control and manipulate the passage of time during play to successfully complete them. Ubisoft’s *The Prince of Persia: The Sands of Time* (2003) uses several such temporal mechanics, which operate as special abilities the player gains related to a weapon called the Dagger of Time. This item allows the player to not only slow the

passage of time, much like earlier games, but also to reverse its passage. Thus, the player may essentially rewind time within the game, allowing him or her to revert (in limited fashion) to an earlier moment within the last few seconds of gameplay. This ability permits the player to correct mistakes made during play and is similar to functions found in other titles, such as Artoon’s platformer *Blinx: The Time Sweeper* (2002), Saber Interactive’s first-person shooter *TimeShift* (2007), and Remedy Entertainment’s *Quantum Break* (2016).

Number None’s *Braid* (2008) employs temporal navigation and manipulation in even more complex fashions, furthering the role of time as a game mechanic. Like earlier temporal navigation games, *Braid* uses a mechanic of rewinding time, and subsequent levels in the game emphasize distinct temporal behaviors and manipulations that must be used to solve puzzles, such as linking the passage of time in the game to the player’s movements. In this instance, game world time moves forward when the player moves the avatar left to right in the game, pauses when the avatar stops, and reverses when movement is made right to left. Such game mechanics thus expand on existing temporal navigation games, and games such as Dontnod Entertainment’s *Life is Strange* (2015) and Superhot Team’s *Superhot* (2016) also explore time-based play. Given the relatively recent emergence of games that emphasize temporal navigation, it seems certain that new ones with even more complex and nuanced uses of time will appear in years to come.

NCSOFT

NCSOFT is a South Korean corporation that specializes in the development of massively multiplayer online role-playing games (MMORPGs). CEO Kim Taek Jin established the award-winning company in 1997. The company gained its high profile a year later, in 1998, when it launched the MMORPG *Lineages*. Since then, it has maintained its preeminence by producing a number of other successful large-scale online games, including *City of Heroes* (2004), *Guild Wars* (2005), *AION* (2008), and *Blade & Soul* (2012), while at the same time developing innovative services in digital platforms for MMORPGs, casual games, mobile games, and character content. In 2018, market-analysis agency Newzoo listed NCSOFT as the world's seventeenth-largest global game company according to annual revenue. The company reportedly earned 421,467,650,710 Korean won (USD 356 million) and employed twenty-three hundred employees in 2019.

NCSOFT's most notable achievements stem from its vanguard role in opening the new era of online gaming to both South Korea and the world. It managed to thrive amid the country's formerly oligarchical business environment, symbolized by family-owned conglomerates such as Samsung and LG. Thanks to the rapidly growing field of internet business that began in the early 2000s as South Korea transformed into a knowledge-based

economy, the company was able to lead the growth of information technology (IT) enterprise in game development. In time, *Lineages* grew to dominate more than half of the content delivery channels serving South Korea's PC bang distribution network, and NCSOFT emerged as the country's leading game company. The company continued to attract Korean players with improved three-dimensional graphics, elaborate cinematic visual storytelling, and unique *Lineage*-style gameplay. Although the game is set in the European Middle Ages, the technological features and narrative structure of *Lineages* reflect the current tastes of Korean players. NCSOFT has contributed much to shaping a strong gaming community in South Korea as playing *Lineages* with friends became a constant feature of Korean social life.

At the same time, NCSOFT successfully expanded its reach internationally. To illustrate, in 2001, NCSOFT established its U.S. subsidiary, NC Interactive, in Austin, Texas. Two years later, it acquired American developer ArenaNet, a video game developer that consists of the core development team for both *StarCraft* (1998) and *World of Warcraft* (2004). This encouraged the company to create the *Guild Wars* franchise, which nowadays allows them to sell five million copies worldwide. Moreover, NCSOFT expanded into Asia with the commercial launch of *Lineages* in Japan (2001), China (2003), Taiwan (2003), Europe (2004), and Thailand (2004). Along the way, the company teamed up with the Taiwanese game publisher Gamania and Chinese publishers such as Shanda, 9 Cities, Tencent, and Giant to specialize in game publishing for Asia's niche markets. Nowadays, it earns most of its revenue from markets in

Asia, in particular those of South Korea, China, Taiwan, and Japan. NCSoft has strengthened its footholds worldwide with the creation of its regional offices: NC US, NCSoft Europe, NC Japan, and NC Taiwan. However, the new release of the mobile game *Lineage M* (2017) has further boosted the company's global market performance.

NCSoft continues to emphasize technology innovation as its core investment strategy. To this end, in 2008, it established a research and development (R & D) center. The company emphasized building competitiveness to overcome the piracy that plagues Asia's regional markets of Asia. It remains committed to strengthening its intellectual property portfolio. By 2018, 69 percent of all NCSoft employees were working in its R & D division. The company is also exploring webtoon IP as it persists in enhancing cross-media user experiences based on the published games *AION* and *Blade & Soul*.

NEC PC-Engine/TurboGrafx-16

The Japanese PC-Engine—and its American incarnation, the TurboGrafx-16—was designed by Hudson Soft engineers

and produced by NEC in 1987. It was one of the first home consoles to be marketed as a 16-bit machine and has been associated with many other technological breakthroughs. Its lineup of shooting games and role-playing games (RPGs) managed to capture the Japanese market, but the console ultimately failed on the American front and was surpassed by the Nintendo Super Famicom in its homeland.

The Hudson company founders became interested in electronic entertainment in 1978 when one of their employees, Shinji Nakamoto, demonstrated software to his bosses. The Kudo brothers saw potential in this new market and started to produce games for personal computers. The response to the first Japanese-made entertainment software was overwhelming, and in 1979, the brothers decided to focus solely on this market and renamed the company Hudson Soft. A few years later, Hudson Soft had become one of the most prolific developers for the Nintendo Famicom, creating or adapting more than thirty-five titles, including *Lode Runner* (1984), *Star Soldier* (1986), and a game based on the popular manga/anime character *Doraemon* (1986). However, Hudson's engineers soon felt limited by the technological restrictions of the Famicom, and in 1985, they started to design a new machine. In 1987, Hudson brought a prototype to NEC, the largest manufacturer of Japanese personal computers at the time.

The PC-Engine's processor was based on the MOS 6502 architecture used in many personal computers and game consoles since its introduction in 1975. Thanks to an updated design and production process, the PC Engine version

could operate at 7.16 MHz (the Ricoh variant used in the Famicom/NES, by contrast, ran at 1.79 MHz). In the United States, the console was marketed as a 16-bit contender on the basis of its graphical abilities: it featured 64 KB of video memory and a 9-bit color palette, but most significantly, it could display the majority of these 512 colors on-screen at the same time. The graphical architecture could also handle up to 64 sprites on-screen at once. On top of these cutting-edge specifications, NEC and Hudson decided to bring the notion of expandability in the console world to a new level. An extension bay was integrated in the core system; it was meant to receive many peripherals, most importantly the very first CD-ROM add-on ever released for a video game system, in 1988. The first HuCARDS or Turbochips cartridges typically held 250 KB of data; the format was further developed up to 2.5 MB (20 Mb) in the early 1990s. The main performance bottleneck of the system was the relatively low working memory (8 KB and 64 KB dedicated to the visuals); to handle data-intensive CD-ROM projects, NEC released multiple system cards (HuCARDS that increased the total amount of RAM available) throughout the life of the system.

Many variations of the system have been released in Japan and Europe, such as the CoreGrafx and the PC Engine Shuttle; except for the ill-fated SuperGrafx, these systems were essentially the same. The PC Engine Duo (1991) and Turbo Duo (1992) merged the core system, the CD-ROM, and the Super System Card in the same elegant console. NEC also released a portable version of its system, the PC Engine GT/TurboExpress (1990), which had the same

specifications and could run all the HuCARDS on an impressive 2.6-inch color screen.

The launch of the PC-Engine in October 1987 was met with enthusiasm by the Japanese audience. NEC/Hudson released a few titles during the launch window, including the technically impressive *The Kung-Fu* (with sprites taking up half the height of the screen) and a port of the popular arcade game *Wonder Boy in Monster Land* (rethemed as *Bikkuriman World*). In 1988, NEC released a faithful conversion of Irem's *R-Type* on two HuCARDS. In 1989, *Gunhed* and *PC Genjin* hit the Japanese market; the cute prehistoric hero of the latter would soon become the console's mascot. Since Nintendo's attitude and restrictive licensing fees had generated some frustration among third-party publishers in previous years, NEC and Hudson managed to interest many smaller studios as well as established players. After a public feud between Nintendo and Namco, NEC was pleased to announce that the developer would bring to its console near perfect ports of its most popular arcade titles, such as *Galaga 88* (1987), *Dragon Spirit* (1987), and *Xevious* (1982). From October 1987 to January 1988, one million units had been sold.

NEC redesigned the exterior of the console and its marketing strategy for the North American region. Major gaming publications ran enthusiastic cover stories just before the expected fall 1989 launch. Despite some of the better games being adapted (*Blazing Lazars* [1989], *Legendary Axe* [1989], and *Bonk's Adventure* [1990]), the first year's sales did not meet expectations. Moreover, the expensive CD add-on (\$499.99) along with its few early titles (including *Fighting Street*

[1989] and *Ys Book I and II* [1990]) did not meet a large audience. NEC's console lacked franchises known to Americans; most of its prime titles were made to appeal to Japanese gamers and were not exported to the United States. As a result, SEGA quickly captured 90 percent of the 16-bit market in the United States.

From 1990 onward, many impressive ports of arcade shooting games were released in Japan both on HuCARD and CD format, including *Darius* (1990), *Aeroblasters* (1990), *After Burner II* (1990), *Gradius* (1991), *143* (1991), and *Forgotten Worlds* (1992). *Gate of Thunder* (1992) and its sequel, *Winds of Thunder* (1993), have reached cult status among the genre's fans. Many mecha-inspired shooters were also released (such as *Macross 2036* [1992] and *Spriggan* [1991]), and the late port of *Sapphire*, using the Arcade Card, was meant as a final technological tour de force in 1995. The console also had an extensive lineup of Japanese role-playing games; on top of popular HuCARDS such as *Dragon's Curse* (1990) and *Neutopia* (1989), many game series started to use the CD format more extensively to integrate animated cutscenes and digitized voices, such as the pioneer *Tengai Makyō (Far East of Eden)* (1989), the four *Ys* games, and many games associated with the *Dragon Slayer* franchise.

In Japan, popular manga and anime series, such as *Ranma 1/2*, *Sailor Moon*, and *Cobra*, were translated for the CD-ROM format into adventure games or digital comics/visual novels with minimal interactivity. Along with idol games (*No.Ri.Ko*, one of the first CD releases in 1988), approximately fifty titles that explore data-intensive designs at the expense of engaging ludic formulae have

been released. NEC put a lot of effort into expanding the variety of genres available on its console: pinball simulators (*Devil's Crush* [1990]), strategy games (*Nectaris/Military Madness* [1989], and *Vasteel* [1990]), multiplayer party games (many iterations of *Bomberman*), and even simulation games adapted from personal computers (*SimEarth* [1993] and *Falcon* [1992]) were released.

To this day, the Super CD-ROM's *Castlevania* game (*Akumajō Dracula X. Chi No Rondo*; 1993) is considered one of the best in the series. The crowning achievement of the console—and a testament to the potential of its expandable architecture—came with the adaptation of SNK's *Fatal Fury 2* (1994) and *Art of Fighting* (1994) games on Arcade CD-ROM; these versions were closer to the arcade originals than the Super Nintendo and Genesis ports. In the United States, however, the TurboGrafx-16 was doomed by the lack of known franchises, the release of mediocre games and ports (such as *Yo Bro* [1991], *Impossamole* [1991], and *Nightmare Creatures* [1992]), and NEC's inadequate marketing.

Neo•Geo

The Neo•Geo was an arcade system and home video game system released in 1990 by the Japanese game company SNK (Shin Nihon Kikaku). It was available in two versions, as the arcade-oriented MVS Multi Video System (MVS) and the Advanced Entertainment System (AES) home console. Both variants were built around a 16-bit Motorola 68000 processor, operating at 12 MHz, and an 8-bit Zilog Z80 coprocessor, running at 4 MHz. The Neo•Geo's custom video chip-set was capable of simultaneously displaying up to 380 hardware-scalable sprites in 4,096 colors (from a 65,536 color palette) at a resolution of 320-by-224 pixels. A dedicated Yamaha sound chip provided fifteen high-quality sound channels. In both its arcade and home incarnations, the system used high-capacity cartridges. Although the original specifications capped the ROM size at 330 megabits, a number of second- and third-generation titles employed bank-switching technology to bypass this limit.

The Neo•Geo systems are notable for a number of technological innovations. Similar to the DECO Cassette System and the Nintendo PlayChoice-10, the MVS's modular design allowed arcade operators to change games quickly and easily, and at under \$500 per new release

cartridge, it offered a considerably cheaper alternative to \$1,000-plus dedicated circuit boards. In addition, available in one-, two-, four-, and six-slot versions, the MVS motherboards accommodated up to six individual titles within a single cabinet for significant space savings.

Based on a modified single-slot MVS board (with unique cartridge pinout to prevent the use of the cheaper home cartridges in arcade machines), the AES was the first system to offer direct equivalents of popular arcade titles for at-home play. A two-dimensional powerhouse, it easily eclipsed the 16-bit home consoles of the time. It was also the first system to use memory cards. Interestingly, because the memory cards were also compatible with the MVS cabinets, it was possible to transfer game saves and high scores between home versions and arcade versions of the same title.

The AES was initially conceived as a rental system because of its high price. At launch, a bundle consisting of the console, two controllers, a memory card, and one game retailed for \$649. In an attempt to reduce manufacturing costs and cut down the retail price, in 1994, SNK introduced a CD-based version of the system, dubbed Neo•Geo CD, followed in 1996 by the revised Neo•Geo CDZ. The games were identical to cartridge-based equivalents but suffered from long loading times (both versions used a single-speed CD-ROM drive).

The Neo•Geo's intended successor, the Hyper Neo•Geo 64—a 64-bit arcade platform with three-dimensional graphics capabilities—was a commercial failure. Introduced in 1997, the system was not backward compatible and only received seven games before it was discontinued in

1999. SNK's two attempts to venture into the handheld market, the Neo•Geo Pocket (1998) and Neo•Geo Pocket Color (1999), were also unsuccessful.

Notable Neo•Geo titles include the fighting game series *Fatal Fury* (1991–99), *Art of Fighting* (1992–96), *Samurai Showdown* (1993–2004), and *King of Fighters* (1994–2003) and the run-and-gun series *Metal Slug* (1996–2003). The system also received a number of high-quality scrolling shooting games, including *Last Resort* (1992), *Pulstar* (1995), and *Blazing Star* (1998). The last Neo•Geo game, *Samurai Showdown V Special*, was released in 2004, marking the end of the system's fourteen-year life span.

NetEase

NetEase, Inc., is an internet technology company. Its portal NetEase, or 163.com, provides diverse services, from news,

e-mail services, financial services, educational videos, eLearning (called Netease Open Course), and online shopping (with its subportal *Kaola*) to content such as livestreaming, entertainment, sports, fashion, tourism, and so forth. The most notable business of NetEase, Inc., is its game business and its most popular massively multiplayer online role-playing games (MMORPGs) *Fantasy Westward Journey* (2001; *Menghuanxiyou* in Chinese) and *Westward Journey Online II* (2002; *Dahuaxiyou Online II*). Many of NetEase's popular games developed from Chinese historical epics and classic novels, such as *Journey to the West* (1592). With such traditional themes echoed by players, it is not difficult to imagine nationalism and patriotism infiltrating gaming and game culture.

In 2006, in response to a founder of the game guild named "Kill the little Japs," administrators of *Fantasy Westward Journey* (2001) expunged the seven hundred-member anti-Japanese guild and locked the account of its founder. Subsequently, players continued to self-organize massive anti-Japanese protests online in various blogs and game spaces (Lemon 2006; Kshetri 2009). Political sensitivity did put the game company at risk, and so did social controversy. Although the exact details cannot be traced—as all online reports were removed—the Chinese state also banned *Westward Journey Online II* (2002) for several months because the content of the game allegedly had themes of obscenity and antisocial norms, such as in-game marriage (Wu et al. 2007). As of 2017, *Fantasy Westward Journey* had attracted more than 100 million global downloads and a record of 2.7 million concurrent user count in 2017 (Cowley 2017).

Besides developing its own games, NetEase gained its fame by publishing local versions of licensed games, such as *World of Warcraft* (original, 2004; NetEase version, 2009), *Diablo III: Reaper of Souls* (2014), and *Minecraft* (original, 2009; NetEase version, 2016) to name a few. As of 2016, NetEase was ranked as the seventh public game companies in terms of game revenues, just after EA (with an annual revenue of \$4.28 billion) (Takahashi 2017). However, today, the company Tencent—able to draw gamers directly from its social media, *WeChat* and *QQ*—has surpassed NetEase’s position in terms of game revenues. Netease is now diversifying its digital business into other areas, such as music streaming, online learning, and e-commerce.

Netherlands, The

In 2016, an article in a major Dutch newspaper caused ripples throughout the Dutch game industry and gaming-related universities. The article paints a picture of the game industry’s overstated growth potential and warnings about false promises. It suggests that far too many universities were drawing in large numbers of students who, after college, would meet an industry with too few job opportunities. The industry was swift to respond by explaining that many students, in fact, do find work, but not always directly in the entertainment gaming industry. Instead, they wind up in the applied gaming sector and related fields of multimedia design, software development, and other areas within the larger Dutch media and technology landscape.

As Nieborg and De Kloet point out, the Dutch gaming sector, like many other European gaming sectors, is oftentimes framed within a master narrative of potential. And with success stories such as triple-A developer Guerilla Games (the *Killzone* series, *Horizon Zero Dawn* [2017]) and indie developers such as Vlambeer (*Super Crate Box* [2010], *Nuclear Throne* [2015]), the attractiveness of the Dutch gaming sector is clear. However, such narratives function as a

technological imaginary growing a speculative bubble that, in turn, draws in investors and state subsidies and helps to establish more game programs within Dutch Universities. While this speculation may indeed surpass the revenue potential of the industry, the industry's response to the 2016 news article claims that this depends on one's definition of the scope of the Dutch game industry as one primarily dedicated to entertainment or one that can be expanded far beyond. Here, we argue for the latter, showing that entertainment and more applied purposes of game design are both key in understanding the Dutch gaming industry.

The history of the game industry in the Netherlands starts early on with the acquisition of U.S.-based Magnavox, creator of the first game console, the Odyssey, by Dutch electronics company Philips in 1974. In the years after, Philips would release a string of early home consoles under both Magnavox's Odyssey banner as well as its own Telespel and Videopac brands. As Lenting notes, Philips seemed to put a clear mark on the focus and scope of the Dutch game industry by framing its products as home computers rather than gaming consoles. First, this means that a machine like the Philips P2000 was never meant exclusively for entertainment gaming but also for education and business purposes, thereby inadvertently adding nonentertainment software to the scope of the Dutch game industry. In fact, Philips's hardware also came with cartridges with software meant to introduce consumers to simple forms of computer programming. Second, by framing their hardware as home computers, Philips put the focus of the Dutch industry squarely on PC

games. This was further emphasized by a lack of big console publishers and a vibrant bedroom coder scene. The Netherlands, like many European countries, therefore also never fully entered the console and arcade industries dominated by the United States and Japan, which also means the game industry crash of the 1980s left the Netherlands relatively unscathed.

Although games for Philips's hardware were never produced in the Netherlands, software and game development in the Netherlands did start soon after the release of the Commodore PET in 1977. This early development took place among hobbyists experimenting with this early home computer. In the early 1980s, the activities of these bedroom coders would result in the first generation of game developers such as Radarsoft en Aackosoft publishing games for the Commodore 64 and MSX computers from the mid-1980s onward. Their games were a combination of original work and clones of existing games and again offered both pure entertainment genres as well as educational titles.

In the 1990s, this dual approach to both entertainment and education remained. After a failed effort to work together with Nintendo to develop its first CD-ROM-based console, Philips wound up releasing its own disc-based CD-i console in 1991. Its high price tag and confusing, unfocused marketing (one machine for games, films, music, and education) resulted in a costly flop for the company. The CD-i is now mostly remembered as one of the only non-Nintendo platforms to see the release of several (abysmal) *Zelda*-based games—a leftover from the original Nintendo collaboration. Another Dutch company did

succeed in combining entertainment and applied games: software developer Davilex had a string of successes, such as the distinctly Dutch *A2 Racer* (1997) and educational *RedCat* series, both of which remain among the most well-known national games among older Dutch gamers.

The 2000s saw the start of the first game-focused programs at Dutch universities of applied science. As Nieborg and De Kloet point out, releases on the PlayStation by developers such as Guerrilla Games, and the activities of the then new (but now defunct) Dutch publisher Playlogic made setting up a games curriculum viable and attractive. Furthermore, students from the first few cohorts became founders of several still existing and successful game companies, such as Vlambeer, Ronimo, and Monobanda. This flurry of activity was further supported by a large amount of public funding by the Dutch government, which, spread over various subsidy programs, spent many millions of euros. The focus of these subsidies, however, was mainly aimed at applied gaming, a sector that has always existed in parallel and often close cooperation with the entertainment branch of the industry.

The decade of the 2010s reaffirms this dual nature of the Dutch game industry. The self-published *Games Monitor 2015*, which show the developments and trends in the industry of that year, revealed there were as many developers making entertainment games as there were making applied games. However, the most recent *Games Monitor* (2018) also specifically emphasizes a growing entertainment sector, with the number of companies now surpassing those focused on applied games. This trend is mostly composed of gaming graduates starting their own

small companies seeing new possibilities for self-publishing their games on new distribution platforms, such as Steam, Android, and iOS, and exploring new revenue models, such as in-app purchases and advertising, crowdfunding, or patronage. While this initially sounds like the industry is finally living up to its (at times) strategically exaggerated potential, new digital platforms, such as those found on smartphones, with their own particular hit-driven markets, are increasingly difficult to break into for newcomers. As such, many new, smaller companies do not have long life spans. The rise in attention to the business of developing and marketing games in design schools and within successful incubator organizations, such as the Dutch Game Garden, does present a more solid jumping-off point for those entering the industry both in entertainment and applied gaming sectors.

As was also argued in the 2016 newspaper article, the Netherlands as a country is too small to sustain a market in which all gaming graduates wind up working on entertainment. However, from its beginning, the Dutch industry has always sought to diversify into applied markets, which has thoroughly shaped this dual focus of the Dutch game industry, creating an industry where entertainment games stand on equal footing with applied games. More so, students with a game design background are now found in every sector of the media and technology industry, showing that an industry's perceived but also *actual* potential does not just lie in its most visible and recognizable product, the game.

New Zealand

New Zealand had a quite isolated and remarkably active early microcomputer, console and, arcade game scene in the late 1970s and early to mid-1980s, before the wave of global commercial hardware and game titles rolled in. Although it is difficult to determine the dates of release of many computer systems and consoles in New Zealand, they usually lagged behind the rest of the world by a year or more (Swalwell 2005, 1). For instance, the IBM PC (or clones) were not yet available in 1982 and only became “a commodity” in 1986 (Doran and Trotman n.d.); the Sinclair ZX81, released in the United Kingdom in 1981, was still selling for NZD 199 in 1983 and for half that price in 1984 (Swalwell 2007, 270); and the Atari VCS 2600, released in the United States in 1977, was presumably still sold in New Zealand (at a low price) in the mid-1980s (Swalwell and Loyer 2006). The reasons for New Zealand’s relative

isolation might be found in the long distance from the rest of the world and the associated transport costs and import restrictions (finally lifted after 1984), together with tax incentives that invited local production (Kraemer and Dedrick 1993, 20; Swalwell 2005).

The majority of popular computer systems were eventually released in New Zealand. Initially, as in the rest of the world, due to high prices, computers were predominantly owned by companies and government institutions, not by individuals. Schools and high schools used a wide variety of systems, for example, the Macintosh Plus, different versions of the Apple II, and the Acorn BBC Micro, but also the basic Sinclair ZX81. In 1982, the Apple II was offered at a discounted price of NZD 1,200 to schools (“normal school price” NZD 4,812; *Bits & Bytes*, 1982, 12), and the BBC Micro advertised for NZD 1,595, with “education prices available” (5). The Australian retail chain Dick Smith sold a number of computers that were copies of other systems, the most notable being the System-80, a TRS-80 clone that retailed for NZD 1,200 in 1980 (Stewart n.d.) and for NZD 1,295 in 1982 (this price and the following prices, *Bits & Bytes* 1982, 35). Other popular home computers included the Atari 400 (NZD 1,295), 800 (NZD 2,695), and XE; the Commodore Vic 20 (NZD 899) and its successor, the C64; the Sinclair ZX81 (NZD 199); and the ZX Spectrum. Of these, the Commodore 64 was the most advanced and proved popular. The Acorn BBC and the Electron, which was a downgraded version of it, might be best known for *Elite* (1984) and *The Sentinel* (1986; released as *The Sentry* in the United States), which were originally written for them. New Zealand

was one of the few places outside Japan where the SEGA SC-3000 (a SG-1000 console with an integrated keyboard) had a “wide and loyal following” (Swalwell 2005, 5). Collectors Wheeler and Davidson “have assembled a list of locally published software . . . [with] some 300 titles of tape software, not counting cartridges, disks, or typed-in programs” (Swalwell 2009, 268). The Amstrad CPC competed against the Commodore 64, and the Atari ST against the Commodore Amiga. Beginning in the early 1980s, the Polycorp New Zealand Ltd. developed and marketed the Poly (in three versions, 1, 2, and C), a computer aimed at educational settings (*Bits & Bytes* 1982, 11). It featured an 8-bit Motorola 6809 processor, 64K RAM, color screen, and network capability (14). Peripherals included a 600K disk drive, a cassette recorder, and a printer. It was locally manufactured with 70 percent New Zealand parts, including the circuit boards (13). Various programming languages (e.g., BASIC, Pascal, Logo), games, and educational software (Doran and Trotman n.d.) aligned with local school curricula were available. Discounted school prices went from NZD 4,110 for a nonnetworked single-user system with cassette recorder interface to NZD 8,090 for a networked unit with a disk drive (*Bits & Bytes* 1982, 14).

Not all consoles popular in Asia, the United States, or Europe made it to New Zealand. Consoles apparently not available were Coleco’s ColecoVision, the Mattel Intellivision, and the GCE/Milton Bradley Vectrex (Davidson n.d.). The Atari 2600 was still being sold in 1983 (Swalwell and Wilson 2004), although “only a few” game cartridges were officially released and “hardly any

third-party titles” were available (Davidson n.d.). Its most popular clone was the Kingsway system with sixty-four built-in games (Davidson n.d.). Other available consoles were the Atari 7800, SEGA’s SG-1000, the SEGA Master System, the SEGA Mega Drive, Nintendo’s Game & Watch, the Nintendo Entertainment System (NES), and the Super Nintendo Entertainment System (SNES). Several consoles appear to have been made in New Zealand: the Sportronic (late 1970s and early 1980s, a *PONG* [1972] clone build by Osborne Professional Electronics for Sportronic TV, a division of the Spectrum Group of Auckland; Brown 2003); the Tunix Home Arcade (possibly identical to the system known as the Leisure Vision; Swalwell 2005, 5); the Fountain Video Game and Force II Video System (both licensed versions of the 1976 Radofin 1292 Advanced Programmable Video System); the Videosport made by C.V.T. Industries of Auckland (see Swalwell 2006); and Grandstand’s Database and Mark III Video Game (sold in the United Kingdom as Programmable Game; for both consoles, eight game cartridges are known to exist; Davidson n.d.). Both the Tunix as well as the Database may appear to be clones of the Emerson Arcadia 2001 console, but they merely shared the same (possibly licensed) core (Davidson n.d.; Swalwell 2005, 5). Grandstand also rebranded and sold Orbit Electronics’ UVI Computer Game as Video Master (also an Arcadia clone; Davidson n.d.). A console by David Reid Electronics may “have [only] sold in very small numbers” (Swalwell and Davidson 2016, 1).

The arcade business was considerable in New Zealand, given the relatively small size of its population. As many as a

dozen companies may have been involved as manufacturers, importers, distributors, and game producers, and there were local offices of larger companies (Swalwell 2005, 3; Swalwell 2006, 14; Swalwell and Davidson 2016, 88). A popular practice was to only import the game boards but build the cabinets locally to save on shipping costs and to take advantage of concessions for goods that were (partly) manufactured in the country (Swalwell and Davidson 2016, 3).

Kitronix (Kitset Electronics Limited) of Auckland, founded by Ralph Stevenson, was a game producer whose games included *GP Racer* (1974?), *Galactic Invaders* (1980), *Malzak* (1980; about five hundred machines sold), *Malzak II* (probably released shortly after *Malzak* as a slightly different version of the game), and *Panix* (unknown year), possibly inspired by the arcade game *Space Panic* (1980) by route of the Apple II game *Apple Panic* (1981) (Swalwell and Davidson 2016, 96). Kitronix made its own metal eight-way joysticks and metal buttons (92) and also exported arcade machines to Australia (Swalwell 2005, 5).

A number of companies were operating out of Christchurch, including George Rait's Rait Arcade Games, Taito-tronics, Chris Looman's Advance Automatics, and Chris Chaston's Chastronics. Rait Arcade Games produced games in the early 1980s (such as *Azurian Attack* [1982]); Taito-tronics was a local agent of Taito Japan, and Advance Automatics was an agent for Atari, Stern, Williams, and Gottlieb (Swalwell 2005; Swalwell and Davidson 2010). Chastronics was one of the largest suppliers of arcade games in New Zealand in the early 1980s, although "most of the [game] boards appear to be bootleg versions" (Davidson n.d.).

Other companies focused on distributing computers and consoles and coding and selling software for them. Among them were Scorpion Software/Flexisoft, Poseidon of Tokoroa, and Softtime. Les Kenyon's Grandstand of Auckland worked "in partnership with R. R. Fenton (later Mattel)," importing handheld/tabletop consoles "from Japan and Hong Kong" and building cases and assembled devices locally (Swalwell 2005, 5); they were also a distributor for the SEGA SG-1000 and SC-3000 systems until 1986, when the company focused on Amstrad instead (Davidson n.d.). Auckland's Monaco Distributors sold the Atari 2600 console and cartridges and the Tunix console. The Australian-based company Home Entertainment Suppliers also distributed Atari cartridges in New Zealand (Davidson n.d.). In the 1980s, arcade machines were not only found in amusement arcades but also virtually every takeaway bar. These machines were popularly called *Spacies* (from *Space Invaders* [1978]), and children spent hours hanging out at the local takeaway shop playing *Spacies*.

The overwhelming majority of magazines in New Zealand were (and still are) imported from the United Kingdom. There were, however, some local publications featuring home computers and consoles. The Christchurch-based magazine *Bits & Bytes*, which published its initial issue in September 1982, was the first magazine to focus on the developing microcomputer scene (Stewart n.d.). NOMAC published *Computer Input* magazine beginning in October 1983 and *SEGA Computer—The Official Magazine of the SEGA User Club of New Zealand* in July 1984. *SEGA Computer* was set up by Grandstand and centered around (game)

programming (most of it in BASIC but some in machine code as well as hints, program listings, and program dissections), background information (e.g., on scrolling, optimized RAM usage, random numbers, hidden commands, error messages), and even some hardware hacks (such as a household burglar alarm).

Given the initial and sometimes continued limited availability of software, many early computer games were created by amateur enthusiasts, given away, and copied freely, especially for computer systems used in schools. The September 1982 issue of the Christchurch-based magazine *Bits & Bytes* presents ten user clubs for various systems (35ff.), focused on, for instance, users helping each other, creating and sharing software, and publishing newsletters. Computer systems such as “the Commodore, Amiga, and TRS-80 systems” sparked “high levels of hobbyist activity” (Swalwell 2009, 273). Over two hundred “locally developed game titles” for microcomputers written in the 1980s in New Zealand have been documented so far (Swalwell and de Vries 2013). The user-created games only had limited distribution, and many titles are now considered lost. Games were also typed in from program listings published in magazines, a common practice at the time, even in other countries. In the late 1980s, cassettes were replaced with disks for data storage. Because commercial games were copied and swapped, they began to feature copy protection, which was subsequently removed by cracking crews, who branded the games with intros, which happened in New Zealand as in other places.

The evidence of early computer games popular in New Zealand appears sketchy

today. The main problems that hamper attempts to access, preserve, and distribute games are “outdated hardware, deteriorating software, and intellectual property restrictions” (Swalwell 2009, 265). Early digital artifacts, such as games, were only created relatively recently in the 1970s and 1980s and are still covered by copyright. The biggest challenge for preservation efforts apart from “finding the people who wrote or published titles [and] gaining their support . . . is determining whether they still legally own copyright” (269). This situation leaves many titles in limbo (Swalwell 2009) as orphan works or abandonware that either cannot can be legally used or disseminated or only with limitations. The issue is specifically pressing in regard to media whose “physical platforms are likely to decay well before their copyright protection expires” (Corbett 2010, 184).

For a country such as New Zealand, the issues of orphan works and abandonware impact work on cultural heritage more immediately and significantly than they impact the economy (Corbett 2010, 196; Swalwell and de Vries 2013). In 2004, the New Zealand government issued its Digital Content Strategy, “which contained provision for a National Digital Heritage Archive (NDHA), to be set up by the National Library of New Zealand” (Swalwell 2009, 267), and Digital Strategy 2.0 was launched in 2008. Although the singularity of many game titles is increasingly realized, the collecting and archiving is left to private persons and initiatives (Swalwell 2009). Attempts to officially preserve software, such as legislative support, is lacking; many issues still need to be addressed (Corbett 2010, 193ff.). Current provisions for preservation efforts by national and

international copyright agreements, such as the Berne Convention, may well be “inadequate” (181) or insufficient, and agreements such as the Vancouver Declaration still lack implementation (Swalwell and de Vries 2013).

Newsgames

The term *newsgames* was originally coined by media scholar and game designer Gonzalo Frasca to describe interactive computer simulations of political cartoons known as *editorial newsgames*. They now include infographics, documentary, literacy, and community video games that function as journalism. Unlike the fantasy content of traditional video games, newsgame content focuses on reality, and gameplay functions as a tool for understanding the world.

Newsgames operate at the intersection of video games and journalism. Designed in response to actual events, they often deal with larger social, political, and economic issues. *Spent* (2011), for example,

places the user in a scenario in which he or she has just lost his or her job and must make \$1,000 last for one month. A financial challenge is also central to *Rebuilding Haiti* (2014), which demonstrates the difficulty of financial planning faced by Haiti in the wake of its major earthquake. Newsgames are persuasive in nature and seek a wide audience in service to the public interest. Most are therefore available online and are played through a web browser. The internet, rather than console gaming, and digital journalism are direct extensions of newsgames.

As a supplement to traditional news, newsgames offer the context and analysis of journalistic documentaries. Newsgames typically draw from the methods of print features or documentary video journalism to probe beneath headlines. The social, cultural, and economic dimensions of life in gangs in inner-city Chicago is emphasized in the adventure game *We Are Chicago* (2017). This narrative-based game borrows from Rockstar Games' visual aesthetic and gameplay for a blend of activism, advocacy journalism, and documentary filmmaking drawn from the real stories of inhabitants of a South Side neighborhood. The game's immersive experience encourages empathy for those negotiating school, gang, and family life in a city plagued by unprecedented murder rates.

Newsgames often have a persuasive intent. The intimacy of the gaming experience through an avatar based on a real, rather than fictional, subject carries social and psychological implications, especially through the heightened sense of empathy that can be a catalyst for political change. Games designed to elicit heightened empathy treating the

immigration crisis include *Against All Odds* (2007), *The Refugee Challenge* (2014), and *The Migrant Trail* (2014). The open-world game on the Iranian Revolution, *1979 Revolution: Black Friday* (2016), by iNK Stories, immerses players in the context of war. But instead of adopting the perspective of a combatant as in traditional first-person shooters such as *Call of Duty* (2003), the user is tasked with covering the event as a photo-journalist. This use of gameplay to expose the process of journalistic production is also evident in *Al Jazeera's* game *Pirate Fishing* (2014), which places users in the role of a reporter to experience the ethical challenges and risks inherent in policing illegal trafficking by sea.

The use of gameplay mechanics and logic to convey information and present a point of view provides a valuable interactive supplement to traditional news. Given the highly immersive and empathic potential of newsgames, their producers bear greater responsibility than their fictional counterparts for the transparent communication of their intentions and biases. Newsgames overlap with advergames, such as the quiz appended to *Cocainenomics* (2015) the sponsored content digital long-form feature on the Pablo Escobar drug trade created by WSJ Studios to promote the Netflix series *Narcos* (2015). The ethics of newsgames has been called into question by critics who allege that the gamification of news trivializes serious issues. However, since 2003, innovations in the genre have demonstrated how video games can perform as effective journalism. Among the many quizzes and games that have augmented digital journalism are the German website *Opinary*, *You Draw it* (2017) from the *New York Times*, and

Einheitreise (2017) from the *Berliner Morgenpost*. *Propublica* used its renowned investigative storytelling and data journalism for the production of *HeartSaver: An Experimental Game* (2013).

The use of quizzes and interactives to attract an online news audience began with *BuzzFeed* in 2008. Despite the platform's focus on lists as the main mechanism for expanding its audience, *BuzzFeed* maintained its use of quizzes to draw additional traffic. The strategy paid dividends, as the market for gamified journalism and newsgames soared within the next six years. *Slate's* game *Name Generator* (2014) became the most popular interactive feature in its history, and the *New York Times's* dialogue quiz was its third most popular piece that year (Lichterman 2015).

GAMES AS JOURNALISM

Gaming formats enhance the core democratizing function of journalism to expose policy, power, ideology, and self-interest that is otherwise less apparent in traditional news stories. *Half the Sky Movement: The Game* (2013), based on the nonfiction book and PBS television series *Half the Sky: Turning Oppression of Women into Opportunity Worldwide* (2012), represents gamified journalism that directly advocates for oppressed populations in more empathetic and powerfully intimate ways than stereotypical "soft news" associated with escapist entertainment media. The activist mission of the organization Games for Change represents the new wave of advocacy newsgames, including those on behalf of the disabled in *Beyond Eyes* (2015), members of the LGBTQ community in *A Closed World* (2011), and

children of nations at war in *Lila and the Shadows of War* (2016).

Open-world games, like many news-games, thrive on “procedural rhetoric” that simulates how things work through models (or systems) that users can interact with. Narrative remains essential to that procedural rhetoric because stories experienced through games, as with stories told through traditional narrative media forms, communicate relational and emotional information. Narrative journalism is enhanced by gaming according to the principle that the human mind is not inclined to function like a fact-memorization machine but instead operates according to affective association that draws on empathy. Gaming is particularly adept at eliciting empathy by placing the user in the place of others for a simulated experience of their emotions to build emotional memory. Newsgames are effective at conveying narrative because stories establish frameworks inside of which the players’ objectives become significant and meaningful from a human perspective.

Night Journey, The

Bill Viola and USC Game Innovation Lab’s *The Night Journey* (2007, 2018) was an early experimental art game developed as a collaboration between the media artist Bill Viola and the USC Game Innovation Lab, specifically game designer Tracy Fullerton and developer Todd Furmanski, art director Kurosh ValaNejad, and audio designer Michael Sweet. The game development was supported by grants from the NEA media arts program and the Annenberg Institute at USC after an initial concept phase sponsored by Intel.

The goal of the game design was to meld the media of video art and games to create an experience that evoked the spiritual journey, a theme that is found throughout Viola’s prior work. To do this, the team worked with an archive of Viola’s videos, using them as inspiration for the design of the explorable 3-D world as well as media for the in-game “reflections” and “dreams.”

The game mechanics are based on the idea that the archetypal spiritual path always involves a kind of reflection that reveals mysteries beyond the surface of one’s experience in the world. In the game, the reflection mechanic does just this, merging Viola’s eerie videos with a heavily postprocessed black-and-white game environment, creating an effect of visions arising from the landscape. These visions, or reflections, as they are called in the game literature, hearken to a set of themes in each of the main areas of the landscape. The desert area reflections are visions of the spirit emerging. The underwater area reflections depict the submerging of the body in a kind of baptism. The mountain area reflections are a

retreat into the self, the heart, and darkness. The forest area reflections depict the encounter with the Other, in the form of animal spirits. These reflections are echoed again in dreams that the player has at the end of each night cycle of the game.

The game takes place over the course of six cycles, which equate loosely to the six bardo states of Tibetan Buddhism. In each of these cycles, the player is dropped into a new place in the world to begin that day's journey. Along the way, the player may find special locations that transition the game into a very different internal world. He or she may also encounter ghostly inhabitants of the world. It is unclear whether the world the player journeys in is the "real" one or the imagined one, and it is unclear whether the images that are seen at the end of each day are dreams or memories. The abstract nature of the gameplay is intended to invite introspection about the imagery and the nature of the spiritual journey.

The Night Journey premiered in its exhibition format at the SIGGRAPH art gallery in 2007. It was subsequently shown in this format at a number of galleries and festivals around the world for the next decade, including the Museum of the Moving Image in Queens, New York; the Nam June Paik Art Center in Seoul, Korea; the ZKM | Center for Art and Media in Karlsruhe, Germany; and the Museum of Design in Atlanta, Georgia. It was awarded Most Sublime Game at IndieCade 2008. In June 2018, a home version of the game launched for PlayStation 4, Windows PC, and Macintosh.

Nintendo

Nintendo was founded on September 23, 1889, by Fusajiro Yamauchi as a manufacturer of a Japanese type of playing cards known as hanafuda. While Nintendo's name is most commonly translated as "leave luck to heaven," others have argued that the name simply means "the company allowed to make hanafuda cards" (Gorges 2012).

By the mid-1930s, Nintendo was the largest card manufacturer in Japan. By the 1960s, however, the market for playing cards waned, and Nintendo experimented with a wide variety of businesses, including a taxi company, instant noodles, a television station, and even a "love hotel" that rented rooms by the hour (Gorges 2012).

Around 1970, Nintendo released an extendable toy arm known as the Ultra Hand that became a surprise hit and would chart the course for Nintendo's future. Invented by Gunpei Yokoi, the Ultra Hand would sell 1.2 million units and led Gunpei to create a number of other toys, including a periscope, a pitching machine that threw softballs that could be safely used indoors, a "love tester," at-home light gun games, Color TV-Game systems that played PONG-like

A Super Nintendo Entertainment System (SNES) console and controller atop a spread of SNES cartridges. (Robtek/Dreamstime.com)

games, and even “laser” shooting ranges in former bowling alleys (Gorges 2012).

Although Shigeru Miyamoto credits *EVR Race* (1975) as Nintendo’s first video game, *EVR Race* was an electromechanical game rather than an electronic game, and though it was Nintendo’s first entry into arcades, it was more in line with other electromechanical games, such as slot machines or pinball than video games, and is therefore not Nintendo’s first arcade video game (Iwata n.d.). *EVR Race* was a horse racing game playable by up to six people. It was quite a large game that used a videotape system to show the “races” for which players would try to guess the winning horse. Because it was quite large and mechanical in nature, it was prone to breaking down and required a great deal of maintenance (Iwata n.d.).

Nintendo released its first purely electronic video games in 1978 with the release of *Computer Othello* and *Block Fever*. The company then entered the handheld gaming market in 1980 with the Game & Watch series. Allegedly inspired by seeing a man on a train idly pressing buttons on a handheld calculator, Gunpei Yokoi created this precursor to the Nintendo Game Boy. The Game & Watch games were fairly primitive devices that had monochrome LCD graphics and did not have cartridges but were single-game devices. By the time the last Game & Watch game was released in 1991, Nintendo had released fifty-nine games in the line in a number of form factors (Gorges 2012). In addition to being Nintendo’s first handheld series, some of the Game & Watch games had features that Nintendo would reuse in

the future, such as the X-shaped directional thumb pad, dual screens in a configuration similar to that of the Nintendo DS, and the form factor of the Game Boy Micro (Gorges 2012).

In 1980, Nintendo also branched out to North America by opening an office in New York (in 1982, it would move its headquarters to Seattle, Washington) (Kent 2001). It was during this time that the *Radar Scope* (1980) arcade game was released in North America. The first game to be released in the United States under the Nintendo name, *Radar Scope* was a commercial failure, but it is notable because its hardware would be reused for 1981's *Donkey Kong*, which was the first game by Shigeru Miyamoto and introduced the Mario character (Gorges 2012).

At the time, Nintendo was not manufacturing a home console system; therefore, in 1982, it sold the rights to make a console version of *Donkey Kong* to Coleco, which released the game for the Atari VCS 2600, the Mattel Intellivision, and its own ColecoVision (Kent 2001). The decision to sell Coleco the rights for console versions of *Donkey Kong* came back to haunt Nintendo in 1983, when Coleco attempted to release a version of *Donkey Kong* for its own ADAM computer, which was an add-on to the ColecoVision (Kent 2001). Nintendo had only sold Coleco console rights and had sold home computer rights to Atari, which had made a version of *Donkey Kong* for its own line of home computers. Although Coleco claimed that the ADAM was a computer with a video game system built inside, it soured Atari's relationship with Nintendo (Kent 2001).

The effects of Coleco's attempt to release *Donkey Kong* on the ADAM went

far beyond that one game; at the time, Nintendo was developing its own home console, and Atari was negotiating to be the system's worldwide distributor. When Atari found out about Coleco's version of *Donkey Kong*, the negotiations stalled; therefore, in 1985, Nintendo released the console to the American market independently as the Nintendo Entertainment System (NES) (Kent 2001).

This was not the last time Atari and Nintendo had tense business negotiations. The two companies tangled again when Atari attempted to bypass the copy protection system on the NES. This conflict came about when Atari attempted to make games for the NES without receiving Nintendo's permission. Atari did not have the foresight to include copy protection mechanisms in its cartridges, which allowed anyone to make games for the 2600, but Nintendo learned from Atari's oversight and added copy protection to its cartridges, which meant Nintendo controlled how many games a company could release for the NES. When Atari attempted to bypass this copy protection by releasing unauthorized games such as *Tetris* (1984) under the Tengen label, Nintendo took Atari to court and won (Kent 2001).

In the years since the appearance of the NES, Nintendo has released a number of video game systems, including the Game Boy, Virtual Boy, the Super Nintendo Entertainment System (SNES), the Nintendo 64, the Nintendo GameCube, and the Nintendo Wii. According to Nintendo's corporate financial statements, Nintendo made more than \$1.6 billion in 2017; since 1983, it has sold more than 3.2 billion video games and more than 535 million hardware units globally (Nintendo n.d.). Since the release of the NES,

Nintendo has been challenged by seemingly countless console manufacturers, such as SEGA during the SNES and N64 era and Sony and Microsoft during the GameCube and Wii eras. Although some of them have temporarily been more successful than Nintendo, none of them have been in the business as long, and none are as well loved as Nintendo.

Nintendo DS

The Nintendo DS is a handheld video game console that was released in 2004. It has gone through three stages of redevelopment: the DS Lite in 2006, the DSi in

2008, and the DSi XL in 2009. The DSi versions had hardware upgrades, including increased RAM and CPU. In 2011, the Nintendo 3DS was launched. The new console was primarily for playing 3-D games, but it retained backward compatibility with DS games. The DS is highly successful, having sold more than 150 million units globally by the end of 2016. Despite widespread software piracy, games and other software also sold well, with more than fifty-five titles shipping more than a million units by the end of 2009.

DS stands for "developer's system" or "dual screen." The console is characterized by its clamshell design, which features two LCD screens; the lower one is a touchscreen operated by a stylus. The console has two microprocessors, one dedicated to sound and the other to graphics. Games are stored on ROM cartridges that are inserted into the console, and the original DS and the DS lite also have slots for Game Boy Advance cartridges. The DS has a "Download Play" feature that allows for multiplayer games using only one game cartridge; the feature works with local Wi-Fi connections and allows other consoles to download the necessary data from the console with the game cartridge.

The DS can be networked with other DS consoles, either locally or remotely, through the free Nintendo Wi-Fi Connection, and many games make use of this feature. The DS features its own chat program, PictoChat, that allows communication between consoles. After 2006, it was also possible to connect a DS console to the internet; at first, this required the purchase of a separate accessory, the Nintendo DS Browser, but this was eventually made available for free through the DSiWare shop.

The DS was aimed at nontraditional markets. High-profile advertising campaigns prominently featured female celebrities—such as America Ferrera, Nicole Kidman, Beyoncé Knowles, Liv Tyler, and Carrie Underwood—endorsing the product. Some game software catered to and reflected the nontraditional demographic: *Brain Age: Train Your Brain in Minutes a Day* (Nintendo SSD, 2006), *Flash Focus: Vision Training in Minutes a Day* (Namco Bandai, 2007), and *Personal Trainer: Cooking* (Indies Zero/Nintendo NSD, 2008). Traditional Nintendo licenses also sold well, such as *Animal Crossing: Wide World* (2005), *The Legend of Zelda: Phantom Hourglass* (2007), *Mario Kart DS* (2005), *New Super Mario Bros.* (2006), and *Super Mario 64 DS* (2004). However, the top-selling DS game, with more than twenty-three million sold by 2016, was *Nintendogs* (2004), a new title specifically designed for the DS.

Nintendo Entertainment System (NES)/Nintendo Famicom

Few home video game consoles have had such an impact on the video game industry as the Nintendo Entertainment System (NES). Released in the United States in 1985, it revived the market after the video game industry crash of 1983. American retailers that had sold video

games in the last years had been stuck with large inventories of poor-quality cartridges made by soon-to-be-bankrupt game developers that had to be cleared out at ludicrous sale prices. As far as they were concerned, home video game systems had been a momentary trend that had ended. Consumers had been burned by relatively expensive products that were often cheap imitations without much novelty, and confidence in Atari (the market leader) was low following the debacles of *E.T.: The Extra-Terrestrial* (1982) and *Pac-Man* (arcade version, 1980; Atari VCS 2600 version, 1981) for the 2600 system. Many game developers either went under or focused on the personal computer or the arcade market.

Across the Pacific, however, video games were still highly popular in Japan, mainly in the form of arcades but also with home video game systems imported and distributed by Japanese companies. The first Japanese-designed home video game systems were Nintendo's Color TV-Game series, which were dedicated consoles that each played a single built-in game. The first Japanese cartridge-based systems that offered multiple games were the Nintendo Famicom and the SEGA SG-1000, both released on the same day: July 15, 1983. Designed from the beginning as an inexpensive console to manufacture, the Famicom had its launch marred by technical problems and a high failure rate, limiting immediate success. After Nintendo issued a product recall and fixed its hardware, it steadily sold more and more through its first years, to the point where Nintendo's president, Hiroshi Yamauchi, envisioned exporting it to the United States. Minoru Arakawa and Howard Lincoln, heading the newly created Nintendo of America, presented

the Advanced Video System (AVS) at the 1985 January Consumer Electronics Show. At this point, the machine featured a keyboard, wireless infrared controllers, and a tape backup drive. Reaction to the system was lukewarm; the quality of its games was impressive, but merchants were not willing to take a risk on video games, especially given that the feature set of the AVS made it seem like the ghost of recent failures in the home computer market, such as the Texas Instruments 99/4A and the Coleco ADAM. Arakawa and Lincoln had the system redesigned to focus solely on games and rechristened the machine the Nintendo Entertainment System (NES).

It turned out that one of the biggest hurdles the Famicom had to overcome on its journey overseas was the resistance of retailers. To convince them to carry and sell the system, Nintendo had to redesign it to make it appear as something other than a “video game console.” Nintendo developed the Zapper (a light gun) and R.O.B. (the Robotic Operating Buddy), a robot toy that could “play” a few games specially designed for it. The main function of these two additional pieces of hardware was to create a shift in perception for retailers. The new name, Nintendo Entertainment System, together with the accessories portrayed the machine as a technological toy for children and a home station for arcade shooting games, such as *Wild Gunman* (1984) and *Hogan’s Alley* (1984). The Zapper had a degree of success on its own, as fifteen or so games were made compatible with it. R.O.B., however, was for all intents and purposes a stillborn, costarring in only two titles that were launched simultaneously with the console, *Gyromite* (1985) and *Stack-Up* (1985).

Although the reenvisioned NES was a more interesting proposition, Nintendo still had to come up with no-risk policies to persuade retailers: the company would handle all in-store displays and buy back any unsold systems after ninety days. On these conditions, five hundred retailers opted in for the test marketing of one hundred thousand consoles on October 18, 1985.

Aided by an aggressive multimillion-dollar marketing campaign from Nintendo of America, the test launch in New York City was successful enough to expand to Los Angeles. An enduring marketing and advertising campaign put NES sales beyond one million at the end of its first nationwide release year and eventually made it “the best-selling toy in America” in 1988. Nintendo’s market share of the video game business has been reported alternately as 83 percent of North America (McGill 1988, 2), “somewhere between 86 to 93 percent” (Kent 2001, 360), 90 percent of the Japanese market (Sheff 1999, 147), and “85 to 90 percent on both sides of the Pacific” (Sheff 1999, 223). Whichever number one holds to be true, the fact remains: “Nintendo power” was absolute. According to Nintendo’s publicly disclosed historical data, lifetime sales of the Famicom/NES are tallied at 34 million units in the Americas and 61.91 million units worldwide. Its closest competitor was the SEGA Master System, released eight months after the NES in June 1986; its lifetime sales are estimated to 13 million units worldwide, the majority of which were in markets Nintendo had not entered into quickly enough, mainly Brazil, Europe, and Asia.

The 8-bit NES finally died out because of competition from the technologically

superior 16-bit systems. In Japan, the Nippon Electric Company (NEC) released the PC-Engine as a response to the NES's monopoly and seriously threatened it. SEGA tried releasing its 16-bit SEGA Genesis/SEGA Mega Drive console in Japan and North America to expand its customer base, hoping its advanced hardware would sway consumers from Nintendo mania. Incidentally, SEGA's push also dug the grave for NEC's PC-Engine, which appeared in North America as the TurboGrafx-16, but too late and without SEGA's arcade hits to make a serious impact on consumers and convince game developers to work on the console. The announcement of the PC-Engine in Japan prompted Nintendo to develop a follow-up, the Super Famicom, which was released in 1990 in Japan and then in 1991 in North America as the Super Nintendo Entertainment System (SNES). The SNES rendered the NES obsolete save for budget-conscious video game consumers. A new, redesigned version of the console dubbed the "New NES" or "NES 2" appeared in 1993 as a last-ditch effort to maintain consumer interest; however, people had either adopted the Super NES or the Genesis by then, and it did not create much of an impact.

MARKETING STRATEGY AND LICENSING POLICIES

Nintendo's approach to video game production marked a significant shift from its predecessors. Every prior game console, be it the Magnavox Odyssey, Atari VCS 2600, ColecoVision, or Mattel Intellivision, was initially envisioned as a closed system for which only the console manufacturer would develop games for

its own machine. When dissatisfied Atari programmers left the enterprise to form their own game development studio (Activision), Atari sued to prevent them from encroaching on its market, but when it became apparent Atari would lose after two years of trial, it settled for a royalty arrangement. The popularity of home video games led Atari to a generalized laissez-faire attitude, with the belief that consumer demand would keep expanding or sort out the weaker offerings through the principles of the free market. But as many companies flocked to game development for the 2600, the market became crowded with second-rate titles, companies pulled out, and retailers liquidated unsold inventories, contributing to the industry crash of 1983.

Whereas Atari was profiting from its game console sales, Nintendo's business model was to develop a console that had a technological edge on its rivals and yet sell it cheaply—at minimal or no profit. Money would come from the sale of software, so the plan called for no competitors to encroach on Nintendo's private walled garden and steal its customers. However, Nintendo's marketing approach faced a problem: how can a single firm offer enough games to satiate consumer demand? As Nintendo could not feed enough games to consumers, it needed partners. Contrary to Atari, Nintendo would impose very strict regulations of quality control on its partners for the privilege of accessing the walled garden of the Famicom/NES, and the licensing agreements carried hefty prices.

Taito, Namco, and Bandai—three Japanese game developers responsible for, among other games, *Space Invaders* (1978) and *Pac-Man* (1980)—were the

first to be courted by Nintendo on amiable terms to build support for its console. As the Famicom's success grew, Nintendo licensed more developers and exported it to North America. Mindful not to repeat the flood of weak titles that caused the crash of 1983, strict licensing policies were introduced to developers willing to make the lucrative jump over the Pacific. The first of these was that a Nintendo of America licensee was required to submit every game it wanted to distribute through Nintendo for "quality control," and Nintendo had the right to demand any change it saw fit. A properly licensed game would receive the Nintendo Seal of Quality, a device that aimed at inspiring confidence in customers that Nintendo had tested and approved the game. In practice, however, it merely meant that the licensee had paid the fees and done business according to Nintendo's terms. Nintendo was not providing testing services to developers to strengthen its games, but it was monitoring the content carefully to make sure nothing objectionable appeared.

More than anything, Nintendo did not want games such as *Custer's Revenge* (1982) and *Beat 'Em & Eat 'Em* (1982) (two pornographic titles that appeared for the Atari 2600 that caused controversy and ultimately tarnished Atari's image) damaging its efforts to market the NES to kids. The Nintendo of America reviewers examined each game and asked the developer to remove any content that did not fit with Nintendo's family-friendly policy, including illegal drugs, explicit or suggestive sexuality, alcohol, smoking materials, graphic depictions of death, gratuitous or excessive violence, foul language, or ethnic, religious, nationalistic, or sexual stereotypes in

language or symbols. The censors' reach proved wide ranging, to say the least; for example, because the image of the cross was taken to be a symbol of Christianity, it had to be removed from hospitals and tombstones. Such an alteration can be found in Capcom's *DuckTales* (1990), where the coffins in Transylvania bear a cross in the Japanese Famicom version but the letters R.I.P. appear in the American NES cartridge. (See Crockford 1993 to get an overview of the relationship between game developers and Nintendo's regulators.)

Although censorship of content was an issue for many licensees, it was nothing compared to the economic structure involved in producing NES games. Licensees were restricted to developing a maximum of five games per year; Nintendo's rationale was that it would force them to commit time and resources to make each of these games good. In practice, two developers (Konami and Acclaim) circumvented this rule by creating subsidiaries (Ultra Games and LJN) that could also publish a maximum of five games. In addition to the limit of five games a year, every game published on the NES had to be exclusive to that console for a period of two years. In the video game landscape of the time, this usually meant not making another version at all, because in two years' time, a game would have been rendered obsolete by its contemporaries. Perhaps most decisively, however, Nintendo also held a patent for the physical game cartridges of the NES and was their sole manufacturer. Third-party developers had to buy a cartridge lot from Nintendo (with a minimum of ten thousand units), in cash and in advance. The deal was as one-sided as can be conceived: "Nintendo

was paid about 2,000 yen per cartridge by the licensees, about twice what it took to produce them. . . . Companies, particularly small licensees without deep cash reserves, had to risk perilous amounts of capital on large orders if they wanted to gamble on big successes. They shouldered all the risk while Nintendo collected obscene profits” (Sheff 1999, 59). In 1991, the profits in question are said to have been \$1.5 million—*per employee*.

As the NES’s popularity—and the number of third-party licensees—soared, manufacturing and supply issues began to appear. The company rationed its cartridges according to its supplies but also to its own releases. Many claimed Nintendo deliberately denied large quantities of cartridges to licensees when it was on the verge of releasing a big title so that no competition would prevent Nintendo games from selling. Some of the other tactics coined as “inventory management” by Nintendo of America included withholding goods from retailers that sold Nintendo games and systems under the suggested retail price (causing devaluation of Nintendo’s products in consumers’ minds) as well as undersupplying merchants to keep demand artificially high. This approach is a stark contrast to Atari’s *laissez-faire* and illustrates how control over the manufacturing and distribution of games was the keystone of the Nintendo Economic System, the NES behind (and before) the Nintendo Entertainment System (NES).

Eventually, the U.S. Federal Trade Commission (FTC) started an inquiry into allegations of price fixing under antitrust laws. Nintendo settled and managed to get away with what could very well be the most lenient sentence in video game corporate history: it would

issue \$5 rebate coupons to customers who had bought a Nintendo product between June 1, 1988, and December 1, 1990. The coupons could be redeemed on the purchase of a new Nintendo product, thus guaranteeing more sales and profits. Nintendo claimed its various policies on censorship, game release limits, exclusive cartridge manufacturing, and control of distribution were put in place to protect the market from oversaturation and poor-quality titles. This was certainly true to an extent, but many game developers saw them as bullying tactics to coerce them into disadvantageous deals based on Nintendo’s iron grip on the home video game market.

Nintendo’s enforcement of its regulations was ensured by three things: (1) its patent and control on game cartridges, (2) the Official Nintendo Seal of Quality (the absence of which signified to consumers that a title was not “official”), and, more important, (3) the 10NES lock-out chip. This special chip that functioned as a “lock” is the chief difference between the Japanese Famicom and the Occidental NES. Nintendo had copyrighted a strip of computer code that constitutes a “key” and included it in every cartridge it manufactured. If a cartridge without this code (and hence manufactured independently by an unauthorized game developer) was inserted in the NES, the game program was not executed; instead, the console entered a self-resetting routine (usually displaying a blinking blue or gray screen). Unfortunately, over the years, the great majority of NES owners have grown accustomed to seeing these patterns on legitimate cartridges, as hardware degradation caused by dust, moisture, or rough handling often rendered the boot-up code difficult to read.

Unless both the cartridge and console connectors were absolutely clean and properly aligned, the 10NES chip would refuse to launch the game. Compounding this problem, the nonstandard front-loading and push-down design of the cartridge port (that earned the NES its “toaster” moniker) meant cartridges could be slightly nudged (and misaligned) inside the console and made removing dust particles almost impossible without blowing in the port; yet, in so doing, saliva oxidized the connectors and made the console even more difficult to operate afterward. The problem was so widespread that Nintendo marketed the NES Cleaning Kit to help consumers take care of their systems. The 10NES chip turned out to be such a problem that Nintendo removed it from its NES 2, which was also redesigned with a standard top-loading cartridge port.

GAME LIBRARY AND PIRACY

Although the 10NES created multiple additional issues for the NES over the Famicom, it served its primary purpose well. Few unauthorized games appeared for the NES, both because of the technical hurdle of overcoming the lockout chip and because of Nintendo’s unrelenting legalistic pursuit of offenders. The most famous of these cases is undoubtedly the *Tetris* debacle, in which rogue developer Tengen (a subsidiary created by Atari) reverse-engineered the 10NES chip to input the key code in its own cartridges, entirely bypassing Nintendo’s licensing process. Nintendo promptly sued, and the two parties settled, on the condition that Tengen recall its cartridges and refrain from selling them. One notable exception to escape

Nintendo’s wrath was *Wisdom Tree*, an unauthorized developer of Christian games, such as *Bible Adventures* (1991) and *Exodus* (1991); Nintendo did not dare sue for fear of generating bad press in the United States.

In Japan and Asia, where the Famicom had no hardware measures of control, game piracy was a significant problem. Rogue developers would generally produce one of four types of products: multicart games, clones, “retroports,” or original games. Multicarts (multigame cartridges) were collections of games (some of the most popular included seventy-six or two hundred games); most of them were pre-1985 arcade or Atari-era games, and the head count was artificially inflated by counting, for instance, three versions of the same game with different difficulty levels as three games. Clones were created by taking a current game and changing a few minor graphical assets (graphics hacks). Today, one can find on the internet evidence of games such as *Mario 6*, a conversion of *Tiny Toon Adventures* (1991) in which Buster Bunny has been replaced by Mario, and *Mario 16*, which repeats the experiment with *Joe & Mac* (1991).

Retroports are a more interesting phenomenon; here, the pirate game developer takes a next-generation game (destined for the 16-bit SNES, SEGA Genesis, or Sony PlayStation) and adapts it for the 8-bit NES so that markets and consumers technologically left behind can still enjoy the newest games in some form—and the developer, of course, gets to make easy money. A few of the games to have received this treatment include SNES smash hits such as *Super Mario World* (1990), *Contra III: The Alien Wars* (1992), and *Final Fantasy VII* (1997).

Original pirate games are, compared with the other forms of pirate production, more uncommon and generally of lesser quality; they also often reuse graphics from other high-profile games.

The NES/Famicom's success is mainly a result of the restrictive and controlling licensing policies of Nintendo and the excellent quality of its game library rather than its technical superiority. It was an average-power console for its days; Nintendo president Hiroshi Yamaguchi's primary directive—to have it *cheap*—was at odds with being state of the art, but it was cleverly engineered by Masayuki Uemura around a pair of 8-bit processors with one dedicated solely to graphical processing, instead of a costly 16-bit processor. In technical terms, the NES could display up to eight moving objects (sprites) per scanline and up to sixty-four at once on the screen. Each of these sprites could contain four colors taken from the console's impressive palette of fifty-two, and sixteen of them could be displayed at any one time on the screen. These significant capabilities resulted in vibrant, colorful graphics and smooth, fast action. The console was also designed to be expandable via the Zapper and R.O.B. peripherals previously mentioned as well as a music keyboard, computer keyboard, and disk drive, among others (many accessories were released only for the Famicom in Japan).

Most notable, however, is the fact that the cartridges themselves could contain expanded functions in the form of special chips designed by game developers called Multi-Memory Controllers. Nintendo's MMC1 chip introduced battery-backed save games, the MMC2 allowed the console to portray larger moving objects, the

MMC3 optimized split-screen scrolling, and so on.

Finally, one of the NES/Famicom's strong suits was sound and music. With its five sound channels, the console's hardware was leaps and bounds ahead of its predecessors (the Atari 2600 had only two and the Commodore 64 only three). Two square waves and a triangle pulse could simulate different instruments, such as a piano, harp, or guitar and a bass or flute, respectively; a noise channel was mainly used for percussions and sound effects; finally, the DPCM channel could play back sampled sounds—in very low fidelity, as the digitized speech in JVC's *Star Wars: The Empire Strikes Back* (1992) or Konami's *Blades of Steel* (1988) can attest. Using this channel for sampled drum sounds was a more popular alternative (most Konami games demonstrate this as well as the bass drum sound in *Super Mario Bros.* 3 [1988]).

The strength of the NES library can be readily assessed both in terms of games that sold more than one million copies (moreover at a time when the market was less sizable than in later generations) and games that have launched long-term franchises. According to Nintendo's official numbers, in total, five hundred million NES cartridges were sold. Million sellers are, in quantity, chiefly games developed by Nintendo, including its sports series titles (*Golf*, *Baseball*, *Soccer*, *Tennis*, and *F1 Race*) and various others, such as *Excitebike* (1985), *Tetris* (1989), *Dr. Mario* (1990), and *Kid Icarus* (1987). Third-party developers also contributed many games to that canon, including Capcom's *Chip 'n Dale Rescue Rangers* (1990) and *DuckTales* (1989), and many more were adaptations from successful arcade games, such as Konami's *TwinBee*

(1985) and *Gradius* (1985), Namco's *Xevious* (1982), and Capcom's *Commando* (1985) and *Ghosts 'n Goblins* (1985). Numerous high-profile (and lucrative) game series met with success on the NES: Konami's *Teenage Mutant Ninja Turtles*, *Castlevania*, and *Metal Gear*; Capcom's *Mega Man*; Square's *Final Fantasy*; Enix's *Dragon Warrior*; and Hudson Soft's *Bomberman* and *Adventure Island* series. Of course, the real winner in this category of million-selling games is Nintendo and its franchises, which include *Super Mario Bros.*, *The Legend of Zelda*, *Donkey Kong*, *Metroid*, and *Punch-Out!!* Widening the scope of this overview beyond the purely arbitrary one-million-copies commercial considerations to include well-received and influential titles as well—games and franchises such as *Ninja Gaiden*, *Adventures of Lolo*, *Double Dragon*, *Blaster Master* (1988), *Bionic Commando* (1987), *Ice Hockey* (1988), *River City Ransom* (1989), *Crystallis* (1990), *StarTropics* (1990), and *Battletoads* (1991)—merely scratches the surface of the console's offerings.

Today, the NES's legacy lives on in a number of cultural practices. By virtue of its quasi monopoly on the home video game market between 1985 and 1990, the NES is often held as the sole representative of third-generation home video game systems. This gives it the lion's share of the retrogaming current that has been growing in popularity since the beginning of the twenty-first century, in no small part thanks to emulators. Nintendo has been actively capitalizing on its back catalog of games through the Nintendo Wii's Virtual Console channel, where gamers can buy and download selected games from the NES library, and then the Nintendo Switch Online subscription

service. In 2016, the company released the NES Classic (or Nintendo Classic Mini in different markets), a dedicated miniature replica console with controllers that features a fixed library of thirty preinstalled games with no cartridge port. The item was sold-out in record time and became a rarity and collector's item, which led Nintendo toward subsequent production runs before discontinuing the miniconsole in 2018.

The NES also lives through new productions inspired by retro aesthetics. Capcom's thriving *Mega Man* series that debuted on the NES had a follow-up in 2008, *Mega Man 9*, that was made exactly in the image of the original 8-bit games in its structure, general gameplay, graphical aesthetics, music, sound, and, most significantly, difficulty level—much to the joy of retrogamers, whose embracing of the title prompted the developer to release *Mega Man 10* (2010). A slew of independent games soon took on the colors and sounds of NES aesthetics, including Yacht Club Games' *Shovel Knight* (2014), Thomas Happ Games' *Axiom Verge* (2015), and Sabotage Studio's *The Messenger* (2018). Morphcat Games is even releasing a physical NES cartridge of its game *Micro Mages* in 2019.

The aesthetic practice of speedruns, in which expert gamers run through a game in the quickest possible way by careful planning, feats of agility, and exploitation of bugs, also prominently feature NES titles: as of late 2019, one of the largest online speedrun archives, TASVideos, listed 308 movies of NES/Famicom games out of a total of 1806, the rest being split among no less than thirty systems.

Finally, for chiptune scene musicians, the sounds from the NES occupy a place

of choice, seconded by the Commodore 64 and the Nintendo Game Boy. These aesthetic, cultural, and economic afterlives all contribute to the platform's enduring success in video game culture.

Nintendo Game Boy

Since its introduction in 1989, the Nintendo Game Boy line has included seven different models, and, according to Nintendo's investor relations documents, the

Game Boy line has sold more than two hundred million hardware units worldwide. Although the Game Boy is one of Nintendo's most well-known handheld devices, it was not their first. The Game Boy line was preceded by Nintendo's Game & Watch series, which were first released in 1980 (Crigger 2007). Game & Watch games were small devices with a monochrome LCD screen and only a single built-in game. Interestingly, some of the Game & Watch devices had dual screens and looked similar to the much later Nintendo DS line.

In the late 1980s, the Nintendo Entertainment System (NES) was a huge success, and Nintendo decided to make a more advanced cartridge-based handheld game system. The task of creating the new system fell to Gunpei Yokoi, the creator of the Game & Watch line, who would later go on to create the Nintendo Virtual Boy.

Although the Game Boy was not the first handheld game console to use interchangeable cartridges (that honor belongs to Milton Bradley's Microvision that was released in 1979), it was the most successful one of all time (Fahs 2009). However, when it was released in Japan on April 21, 1989, and in North America on July 31, 1989, it was far from certain that it would be a success (Parish 2015). Its two-inch black-and-white screen and Sharp-produced custom Z80 processor were inferior to other handheld consoles, such as the Atari Lynx, the TurboExpress, and the SEGA Game Gear, which all had color screens and were released in the months after the Game Boy hit the market (Kent 2001). In his book *Game Boy World 1989*, Jeremy Parish (2015) argues that these were strengths rather than weaknesses: the processor was well

known to programmers, which meant it was cheap to develop games for it; the hardware itself was cheap; and it had the Nintendo name going for it. Moreover, the low-end hardware meant that its batteries lasted at least ten hours compared with the two and a half hours of competing systems. Although these factors were important, perhaps more important was the fact that the original Game Boy came with one of the most popular games of all time: *Tetris* (1984).

While the original Game Boy was a huge success, Nintendo made several minor changes before releasing a version with a color screen. The first update came in 1995 when Nintendo playfully acknowledged players' desire for a color version of the Game Boy by releasing the original black-and-white Game Boy in different colored cases as part of its "Play It Loud" campaign (East 2009). The next year saw the release of the Game Boy Pocket, which featured a better and larger but still black-and-white screen. The year 1998 would see the release of the third major revision of the system in the form of the Game Boy Light. Slightly larger than the Game Boy Pocket, the Light included an electroluminescent backlight but was otherwise identical to the Pocket. This system was only released in Japan and has become quite valuable to collectors (East 2009).

The Game Boy finally received a color screen when the Game Boy Color was released in the fall of 1998 (Kent 2001). Although this system had the same processor as the original Game Boy, as Nintendo's U.K. site explains, its clock speed was twice as fast as the original system. Using the original chip made it easy for the Color to play not only new color games but also the black-and-white

games of the original Game Boy, which made it quite attractive to customers who could buy the system and have access to the large library of games made for the original Game Boy.

Although faster than the original Game Boy, the Color was still fairly underpowered. According to the *International Business Times*, this was remedied in 2001 when the Game Boy Advance was released. The system featured a 32-bit ARM processor that was said to allow graphics similar in quality to Super Nintendo Entertainment System (SNES) games. Although the system was quite popular, it was criticized for its lack of a backlight, which made it difficult to play in dim lighting. This shortcoming was addressed in 2003 with the release of the Game Boy Advance SP, the fifth major revision of the line. In addition to the backlight, the SP had a new form factor that folded in half when not in use and resembled the original Game Boy when opened.

The final model of the Game Boy was the Game Boy Micro, which was released in September 2005; it was only two inches wide by four inches long. While the Micro was an interesting system, it was released nearly a year after the Nintendo DS. The last game for the Game Boy Advance was released in 2008 (Villapaz 2014).

Throughout its life cycle, the various incarnations of the Game Boy had many accessories released for them. In addition to countless carrying cases and lights, Nintendo also released a camera that took low-resolution black-and-white pictures, a small printer that could print the pictures, a device called the e-reader that read special cards that were swiped through it and would either unlock special

features in some games or load small games, and even a multimedia player. Additionally, Nintendo released the Super Game Boy, which allowed the SNES to play Game Boy games, and the Game Boy Player, which allowed the Nintendo GameCube to play Game Boy games.

Although the Game Boy was not the first handheld system and was never the most powerful, it was the most successful and popularized mobile gaming device. The Game Boy line may be gone, but it lives on through its spiritual successor, the DS line, which was the most popular handheld gaming console line in the world (Schreier 2011).

Nintendo GameCube

The Nintendo GameCube was a sixth-generation game console. A successor to the Nintendo 64 (N64), the system was Nintendo Corporation's fourth entry in the home console market. First unveiled at Nintendo's Space World (now Nintendo World) event in 2000, it was officially released in Japan on September 14, 2001; in North America on November 18, 2001; and in Europe on May 3, 2002.

The GameCube's 486 MHz "Gekko" microprocessor was developed by IBM, based on custom-modified 32-bit PowerPC architecture. The system was equipped with 24 MB of main memory as well as a 16 MB buffer for DVD operations and audio playback. An additional 3 MB of memory were embedded in the "Flipper" graphics processing unit. Developed cooperatively by Nintendo and ArtX (soon thereafter acquired by ATI Technologies), the 162 MHz chip was capable of peak performance in excess of twenty million polygons per second. It supported hardware transform and lighting; full-scene anti-aliasing; bilinear, trilinear, and anisotropic texture filtering; multitexturing; bump

The Nintendo GameCube home video game console system and a controller. (Jorgeprz/Dreamstime.com)

mapping; and 24-bit z-buffering. The custom audio processor was capable of producing sixty-four channels of CD-quality (16-bit, 48 kHz) sound. The system supported standard definition video output, both interlaced and progressive scan, as well as Dolby Pro Logic II-compliant stereophonic sound.

The GameCube was the first Nintendo console to abandon game cartridges in favor of optical medium, the Nintendo GameCube Game Disc—a mini-DVD-based proprietary format developed by Matsushita (now Panasonic). The eight-centimeter disk held approximately 1.5 GB of data. Memory cards, ranging from 512 KB to 4 MB, provided additional, rewritable storage.

Determined not to repeat the mistakes made with the N64, Nintendo consciously aimed to improve relations with third-party developers. Consequently, from

day one, the GameCube enjoyed relatively strong third-party support, both in the form of exclusive and multiformat releases. Competitively priced at \$199, the system launched to generally positive reviews. Nonetheless, the initial sales failed to reach the projected levels, in part because of timing. Released almost a full year after the Sony PlayStation 2, the GameCube found itself in a position similar to that of its predecessor: it was competing against a firmly entrenched rival with an already sizable software library. The situation was further exacerbated by the console's relatively lackluster launch lineup. Although games such as *Luigi's Castle* (2001), *Super Monkey Ball* (2001), *Wave Storm: Blue Storm* (2001), and *Star Wars Rogue Squadron II: Rogue Leader* (2001) were well received, they did not attain the status of must-own titles.

In mid-2002, in response to price drop announcements from Sony and Microsoft, the system's price was reduced to \$149. Despite this, sales continued to lag. With GameCube's disappointing performance in the U.S. market and overseas sales deflating as the yen appreciated against the dollar, Nintendo posted its first loss in history, 2.9 billion yen for the first half of fiscal 2003. Facing considerable inventory backlog (estimated in millions of units), the company temporarily halted GameCube production and, in September 2003, slashed the price to \$99. This finally brought the desired effect. The console continued to sell relatively well throughout 2004 and into early 2005, when interest began to dwindle again, this time because of anticipation of the release of its successor, the Nintendo Wii. Ultimately, the system proved profitable, thanks to low hardware costs and a strong lineup of first-party games. It was discontinued in 2007.

Although not the least successful system of its generation (that dubious distinction belonging to the ill-fated SEGA Dreamcast), with only twenty-two million units sold worldwide, the GameCube was Nintendo's second-worst-selling console, surpassed only by the Nintendo Virtual Boy. Its underwhelming market performance can be attributed to a number of factors. Perhaps most significant of these was the tremendous success of the PlayStation 2, which, by the time of GameCube's release, had already managed to establish a user base of approximately twenty million. Although first-party games sold well throughout the system's life, the same could not be said for third-party offerings. Multiformat titles in particular tended to sell

significantly worse on the GameCube than on the Microsoft Xbox and PlayStation 2, leading a number of developers to withdraw their support for the platform. Compared with its competitors, the system lacked CD/DVD playback functionality, a direct consequence of Nintendo's decision to use proprietary optical drive technology. Moreover, online play support was extremely limited. Released in 2002, the GameCube Broadband Adapter and Network Adapter added online connectivity to the system's features; however, only four games (including one exclusive to Japan) took advantage of it.

An interesting variant of the GameCube hardware was released in December 2001 in Japan. Manufactured by Matsushita and officially licensed by Nintendo, the Panasonic Q was a hybrid game/multimedia system capable of CD, DVD, and MP3 playback and fully compatible with GameCube software. Notable GameCube games include *Pikmin* (2001), *Super Smash Bros. Melee* (2001), *Animal Crossing* (2002), *Eternal Darkness: Sanity's Requiem* (2002), *Metroid Prime* (2002), *Super Mario Sunshine* (2002), *The Legend of Zelda: Wind Waker* (2003), and *Resident Evil 4* (2005).

Nintendo 64

The Nintendo 64 (N64) was a fifth-generation video game console that was released in Japan on June 23, 1996; in

North America on September 29, 1996; and in Europe on March 1, 1997. It was marketed as the first “true” 64-bit system—Nintendo’s superior response to the SEGA Saturn and Sony PlayStation (both 32-bit consoles).

Code-named “Project Reality,” the N64 was developed jointly by Nintendo and Silicon Graphics, Inc. At the heart of the system was a 64-bit NEC VR4300 MIPS central processing unit that operated at 93.75 MHz and was supported by a 64-bit Silicon Graphics Reality Coprocessor. The 62.5 MHz coprocessor handled video and audio processing. The N64 could display graphics in 21-bit color, at the maximum resolution of 640-by-480 pixels, and supported hardware z-buffering, anti-aliasing, texture mapping, trilinear filtered MIP mapping, and perspective correction. The system could theoretically produce up to one hundred channels of 16-bit PCM sound, with a maximum sampling rate of 48 kHz.

The N64 had 4 MB of memory and was the first game console to use a unified memory subsystem (rather than dedicated main, video, and audio memory). In 1999, a 4 MB memory expansion unit was released that allowed for higher video resolution, frame rates, or texture quality in supported titles. A few games required it and would not work without it—notably, *Donkey Kong 64* (1999), *The Legend of Zelda: Majora’s Mask* (2000), and *Perfect Dark* (2000; in single-player and some multiplayer modes).

The N64 was the last home console to use cartridges. Compared with CD-ROMs, cartridges offered very fast loading times and a significant measure of protection from piracy. However, this was offset by limited storage space (up to 64 MB), a longer production cycle (with a

lead time of weeks rather than days), higher production costs (approximately ten times those of CD-ROMs), and a lower profit margin for the developers.

The system, originally scheduled for release in 1995, was delayed several times. Entering the market eighteen months after the PlayStation, the N64 found itself competing against a well-established platform with a global user base reaching seven million and a library of nearly four hundred games. Despite this—and despite the fact that only three games were ready for the Japanese launch—the N64 debuted as the fastest-selling console of its generation. By the time of its North American premiere, approximately 1.2 million units had been sold in Japan. However, the sales soon slumped. Although the system went on to achieve moderate success in the United States, it remained a niche product in Japan.

The N64’s primary weakness was limited third-party support. Although efforts from studios such as Factor 5 (*Star Wars: Rogue Squadron* [1998] and *Indiana Jones and the Infernal Machine* [2000]) and Rare (*Golden Eye 007* [1997], *Diddy Kong Racing* [1997], *Banjo-Kazooie* [1998], and *Donkey Kong 64* [1999]) pushed the machine to its limits, meeting or even surpassing the quality of first-party titles, many developers shunned the system because of the limitations of the cartridge format, choosing to create games for the PlayStation instead. This was the case, for instance, with Square and Enix, the developers of the *Final Fantasy* and *Dragon Quest* series, respectively.

Nintendo attempted to provide an alternative to CD-ROM with its Nintendo 64DD (Disk Drive), a peripheral utilizing proprietary 64 MB writeable magnetic disks. First announced before the launch

of the N64, the attachment was not released until December 1999, and then only in Japan. A considerable number of games were planned for the 64DD; eventually, only nine were released, with the remaining games canceled or released in cartridge format (such as *The Legend of Zelda: Ocarina of Time* [1998] and *The Legend of Zelda: Majora's Mask* [2000]). The Nintendo 64 was discontinued in 2001, having sold just under thirty-three million units worldwide.

Nintendo Switch

The Nintendo Switch is an eighth-generation console developed by the Nintendo Corporation and released in March 2017, following the Wii U, Nintendo's previous console. The system is defined as a

"hybrid console," one that can be used as both a home console and a handheld game. The Switch was first announced on October 20, 2016, with a trailer showcasing its main feature: the seamless transition (or "switch") from one setting to the other (home or handheld), the possibility to play anywhere, and the integration of multiplayer play (local or over the internet). Sold at a price corresponding to \$299, the console was successful from the very beginning, leading to unit shortages around the world. By December 2018, the Switch had sold over 8.7 million consoles in the United States, making it the fastest-selling console in U.S. history. It exceeded the sales of both the PlayStation 4 (PS4) and Xbox One at the same period of their life span (twenty-one months). With over 23 million units sold worldwide less than two years after launch, the console has also rapidly surpassed the total sales of the GameCube (21.74 million) and Wii U (13 million).

Following the low sales of the Wii U, Nintendo hoped to launch a console that would offer a new gaming experience without repeating the same mistakes that afflicted the Wii U's lifetime cycle. For example, the initial reveal of the Wii U focused on the controller (GamePad) instead of the actual console, leaving consumers wondering whether it was simply an extension of the Wii. The Wii U's launch was also problematic due to the absence of big-name titles and technical limits that kept it from competing with the already established PlayStation 3 (PS3) and Xbox 360, much less the soon-to-come PS4 and Xbox One. A lack of third-party games further hurt the system's appeal. Nintendo thus progressively abandoned the Wii U's support

when, in March 2015, then president Satoru Iwata publicly announced the code name of the Switch, the Nintendo NX. After the reveal of the Switch in October 2016, detailed information on the console came to light. Up until launch, Nintendo created a vast marketing campaign, which included multiple trailers, an ad during Super Bowl 50, and a gaming session on *The Tonight Show Starring Jimmy Fallon*. Nintendo's campaign was intended to give the company a fresh start in the console market and to articulate the Switch's concept with greater precision.

The Nintendo Switch comes with a screen, a dock station, and two Joy-Cons. The screen is 6.2 inches, uses LCD technology, and offers a resolution of 1280-by-720 pixels. It also serves as a multitouch-capable touchscreen with a gyroscope and accelerometer. The GPU and CPU are custom-made by Nvidia, and the console's battery (a 4310mAh lithium-ion battery) can last between 2.5 to 6.5 hours, depending on which games are played. To play, users use a Pro Controller or attach both Joy-Cons on small "rails" situated on both sides of the screen. The Pro Controller must be bought separately and offers a traditional controller design. As for the Joy-Cons, they serve as a single controller when attached to the screen. Once detached, they can either be used as one or two controllers. The Joy-Cons include an accelerometer, gyroscope, motion IR camera, HD rumble, and the battery life lasts up to twenty hours. Both Joy-Cons come in different colors; at launch, the only colors available were gray or neon (blue and red). Nintendo now sells bundles with new colors for the Joy-Cons: red for *Super Mario Odyssey* (2017) and green

and pink for *Splatoon 2* (2017), among others.

When placed in the dock, the image is relayed to a television screen through the HDMI port. The dock is slightly larger than the screen and has two USB ports. It is powered by an AC adapter. In 2018, Nintendo shared usage statistics about the Switch: about 50 percent of users play both in the docked and handheld mode, fewer than 20 percent use the console mainly in its docked mode (meaning over 80 percent of the total playing time), and around 30 percent use the Switch mostly in the handheld mode.

As for the games, the console marks a return to cartridges, also named "game cards." The internal storage comprises 32 GB and can be increased when inserting microSDHC or microSDXC memory cards. Games can also be played digitally when bought and downloaded through the eShop, Nintendo's online store for the Switch. Users access the eShop on the main interface of the console, which also shows games recently played as well as apps, news, and announcements and an album of screenshots taken in-game. This simple interface and the sleep mode were designed to allow players to quickly jump into games. As for multiplayer mode, up to eight people can play with two to eight consoles using an ad-hoc local network through Wi-Fi. Online play is also available through Wi-Fi or with a LAN adapter connected to the dock. Even though online play was free for several months, Nintendo launched its online service in 2018, priced at \$20 for a one-year subscription. The subscription gives access to online play and a limited selection of NES games.

The Switch has a wide variety of games, a stark contrast with the Wii U. What is more, many games released or initially planned for the Wii U were ported and updated for the Switch. These games include *The Legend of Zelda: Breath of the Wild* (2017), which won the Game of the Year award in 2017 at the Game Awards, and *Mario Kart 8 Deluxe* (2017). Other notable first-party games exclusive to the Switch are *Super Mario Odyssey* (2017), *Nintendo Labo* (2018), *Pokémon Let's Go* (2018), and *Super Smash Bros. Ultimate* (2018). As for third-party games, *The Elder Scrolls 5: Skyrim* (2017), *Fortnite* (2018), *Diablo 3* (2018), and many more were released. The Switch has also been praised for its ever-growing library of indie games. The Nintendo Switch Lite was released on September 20, 2019.

Nintendo Virtual Boy

Hoping to cash in on the virtual reality (VR) craze in the late 1980s and early 1990s, Nintendo released the Virtual Boy. The Virtual Boy was a dual-monitor VR headset. The headset itself housed all the working components, such as the central processing unit (CPU), and sat atop a table on a bipod stand. To play, the user peered through the neoprene eyepiece and operated a well-designed six-buttoned, dual-directional control pad tethered from the headset.

Nintendo's 32-bit VR machine was originally referred to as the VR-32. After more than two years in development, it premiered at Nintendo's annual Shoshinkai software exhibit in Japan on November 15, 1994. It was released as the Virtual Boy in Japan the following July, followed by an August launch in the United States. The European release was pending but later canceled altogether because of failure of the unit in the Japanese and U.S. markets.

Longtime Nintendo employee Gunpei Yokoi designed the Virtual Boy. In earlier times, Yokoi's own research and development teams had developed the popular Game & Watch series for Nintendo as well as the unparalleled Nintendo Game Boy. As a result, Yokoi's contributions to the company played a large part in transforming Nintendo from a hanafuda playing card company into a toy company. This maneuver eventually led Nintendo into the video game industry.

The Virtual Boy's glasses were the first of their kind on the marketplace. The primary technology implemented in the system consisted of twin mirror-scanning

light-emitting diode (LED) displays, used to create an impression of depth or a 3-D image. This technology was licensed from Reflection Technology, Inc., and it was the first time that Nintendo took an equity position in a U.S.-based privately held company.

The Virtual Boy's monochromatic game imagery was produced with red RTI LEDs, which were chosen over other colors because they consumed less energy, a power-saving maneuver to conserve battery life that was arguably one reason for the Game Boy's success over other handhelds in the previous generation.

The classification of the Virtual Boy is open to debate. Was it a portable gaming system or a home console? It was relatively lightweight compared with other home consoles, yet it was not very portable because it could not be played without being placed on a tripod stand that needed to be set on a hard surface, such as a table. It could be played with an AC adapter plugged into wall, but Nintendo went to great lengths to make sure that it had a solid seven-hour battery life. Nintendo did announce a shoulder mount adapter, to be sold separately, that would remove the necessity of a table and certainly make it more portable, but this adapter was never released.

The unit initially was priced at \$180, with the game *Mario Clash* (1995) included. However, after very disappointing sales, Nintendo officially dropped the price to \$160 after only being on the market for two months. Despite the new manufacturer's suggested retail price, many retailers reduced the unit even further to liquidate it from the shelves, some selling the game machine for as low as \$16.

Many players complained that the unit gave them headaches, and Nintendo

placed a warning on the product that it was not recommended for children under age seven. Furthermore, the unit itself informs players to take a break to rest their eyes after thirty minutes of playing time. This was certainly cause for alarm for some consumers and did nothing to improve units sold.

Although Nintendo had usually found success with its video game products, the Virtual Boy turned out to be a disaster. To date, it is the only Nintendo-released game platform considered to be a failure by both Nintendo and consumers alike, selling a relatively dismal 770,000 units.

As the industry leader, Nintendo was not prone to failure. When the system failed to excite the industry and received less than favorable reviews by the press, Nintendo insisted that Yokoi demonstrate the product himself at trade shows and other promotional events. This was not typically part of a supervisor's job and was intended to demean and insult the previously successful employee. As a result, and after decades of service, Yokoi left Nintendo. Soon after, working for Bandai, he designed the successful WonderSwan portable gaming unit before his untimely death as a result of a car collision.

Fourteen games were released for the Nintendo Virtual Boy in the United States before Nintendo ceased offering support for the system almost exactly a year after its debut in August 1996.

Nintendo v. Blockbuster Video

The court case of *Nintendo of America, Inc. v. Blockbuster LLC* is a lawsuit that

was filed by Nintendo when it accused Blockbuster Video of violating copyright when it made copies of Nintendo's game manuals to rent out with Nintendo's video games. In the end, Nintendo lost the case, with the two companies settling out of court.

As Japanese copyright law features a rental right, or right of lending, which means that companies can refuse to let others rent their products, Nintendo did not let stores in Japan rent or copy its games. But while copyright law in the United States did cover music rentals, there was no such protection in the areas of videos and video games. The Computer Software Rental Amendments Act went into effect in 1990, but it only covered computer software and not home console video games.

Nintendo's response was to sue Blockbuster Video for copyright infringement for the copying of game manuals; the stores were making copies and sending them with copies of the games when they were rented. Blockbuster considered making its own manuals instead and ended up using a third party to create the manuals that would accompany the game rentals. Nintendo and Blockbuster finally settled out of court for an undisclosed amount. Afterward, both companies worked to repair their relationship and went on to further ventures together involving the renting of Nintendo's games. Nintendo even went so far as to release some games that were exclusive to Blockbuster stores, which are now collector's items due to their rarity.

In addition to paving the way for video game rentals in the United States, the court case revealed how copyright laws can differ from one country to another and from one medium to another as well

as the legal distinction that is sometimes made between *computer software* and *video game software*, despite their both being made of computer code.

Nintendo Wii

The Nintendo Wii is a seventh-generation console that was announced by Nintendo in 2004 and released in November 2006; it had sold more than 101 million units by the end of 2016. The Wii quickly moved into a dominant place in the console market, surpassing the Microsoft Xbox 360 and Sony PlayStation 3 in sales within a year of its release.

The console was originally only available in white, but it was made available in black at the end of 2009. The Wii uses a Bluetooth wireless controller called a Wii Remote that is motion sensitive and can

be used as a pointer using infrared detection. The latter feature requires the attachment of an infrared sensor bar to the television screen. The Wii is packaged with an optional Nunchuk attachment to the Wii Remote that is also motion sensitive and is used in many Wii games. The Wii Remote and sensor bar were optimized by the 2009 add-on Wii Motion Plus that was also available bundled with *Wii Sports Resort* (2009). The Wii Remote came with an attachable wrist strap that Nintendo advised be worn around the players' wrists for safety reasons. Even so, numerous cases of injuries and damage to property were reported to have occurred during the course of playing Wii games, either due to overexertion or striking another object with or losing control of the Wii Remote.

The console's media drive could read Wii optical discs and Nintendo GameCube discs, but no other formats. The Wii is fully backward compatible with Nintendo GameCube software, although the online capabilities of that system are not supported; the games still require a Nintendo GameCube controller to work. The Wii connects wirelessly to the Nintendo DS, with several DS games utilizing this feature. This also allows console-specific content to be downloaded and stored on the Nintendo DS via the Wii. The Wii system has a hard drive with a 512 MB capacity and an SD card slot designed for external memory storage. Downloaded content can be stored in the internal hard drive or on SD cards. The Wii features free wireless and Ethernet connectivity and can be connected to other Wii systems for LAN play. The system has a parental lock that prevents children from viewing age-inappropriate content, and the rating of

each game is encoded in the game's disc. Nintendo used the rating system set by the local regulations of each country where the games were released (e.g., in the United States, the Entertainment Software Ratings Board [ESRB] system was used). The system is also locked to a particular region and can only play discs of the same region.

The Wii system's interface is conceptualized as a series of television channels, with six channels appearing automatically: the Disc Channel (where the current game disc loaded into the Wii appears), the Mii Channel (where avatars are created), the Photo Channel, the Wii Shop Channel, the Forecast Channel, and the News Channel. Downloaded games appear as additional channels, and other channels—such as the Internet Channel—may also be purchased. Through the Wii Shop Channel, the Virtual Console and WiiWare services sell downloadable games. Virtual Console sells titles originally released on other consoles, primarily from Nintendo's own back catalog but also classic games from SEGA and other discontinued consoles, which were run through emulators. WiiWare sells original games that were often only available as downloadable content, such as the award-winning *World of Goo* (2008) and *Mega Man 9* (2008).

The Wii system was deliberately designed not to compete with other mainstream consoles (primarily the PlayStation 3 and Xbox 360); this was called the "blue ocean" strategy by Nintendo CEO Satoru Iwata. The strategy included targeting a broader audience that included people who were not generally considered gamers by having an interface, software, and advertising campaigns that appealed

to the young, elderly, women, and casual gamers. The Wii was packaged with *Wii Sports* (2006). Nintendo (and Nintendo-owned subsidiaries) released several high-profile and critically acclaimed games from Nintendo's well-known franchises, including *The Legend of Zelda: Twilight Princess* (2006), *Mario Kart Wii* (2008), *Metroid Prime 3: Corruption* (2007), *New Super Mario Bros. Wii* (2009), *Super Mario Galaxy* (2007), *Super Paper Mario* (2007), and *WarioWare: Smooth Moves* (2007). Nintendo also released several popular games that broadened the Wii's audience. Fitness games, *Wii Fit* (2008) and *Wii Fit Plus* (2009), utilized the Wii Balance Board to calculate the user's body mass index (BMI). Each game included a large number of activities with the intention of providing players a core workout.

Although the Wii had substantial third-party support, with third-party developers working with key Nintendo licenses such as *Mario Party 8* (Hudson Soft, 2007) and *Super Smash Bros. Brawl* (Game Arts/Monolith/Sora, 2008), only a few third-party-designed Wii games sold as strongly as in-house games: *Game Party* (FarSight Studios, 2007), *Just Dance* (Ubisoft, 2009), and *Sports Island* (Hudson Soft 2008). This is attributed to the proliferation of poorly designed, low-to mid-priced games—"shovelware"—for the Wii, which allegedly caused games celebrated by critics, such as *A Boy and His Blob* (WayForward Technologies, 2009), *Little King's Story* (Cing/Town Factory, 2009), *MadWorld* (Platinum Games, 2009), and *Zack & Wiki: Quest for Barbaros' Treasure* (Capcom, 2007), to sell poorly. This was compounded by the family-friendly, casual orientation of the Wii, which meant that

games aimed at adult audiences, such as *House of the Dead: Overkill* (Headstrong Games, 2009) and *Manhunt 2* (Rockstar Toronto, 2007), sold poorly.

Nintendo Wii U

The Wii U is an eighth-generation console released by Nintendo in November 2012. The system had a distinctive and highly praised primary controller: the Wii U GamePad. The Wii U GamePad prominently featured a 15.7 cm embedded touchscreen, along with the more standard directional buttons, analog sticks, and action buttons.

Nintendo had been planning a new console since 2008 under various project titles that were eventually dubbed "Project Café." The remit of the new console was to make key technical improvements in the graphics and network infrastructure of the original Wii, which would enable Nintendo to effectively compete with the Sony PlayStation and Microsoft Xbox systems. The much anticipated Project Café was officially launched as the Wii U at the E3 2011 conference. In the following days, Nintendo's stock fell nearly 10 percent. Analysts believed that this drop in stock price reflected

The Nintendo Wii U console system, at E3 2011. (Antonio Jodice/Dreamstime.com)

investors' possible concern that the Wii U GamePad was both less innovative than the original Wii Remote and would drive up the cost of producing the console.

The Wii U GamePad's touchscreen was designed for what Nintendo called "asymmetric gaming," which allowed for different gameplay objectives and experiences among players within multiplayer games. It could also be used in single-player games as a companion to games being played on a television or by playing games on the GamePad itself. The GamePad was connected to the Wii U wirelessly and supported near-field communication (NFC), which allowed the Nintendo Amiibo series to be activated by the GamePad as well as other Nintendo products, such as the trading cards from the 3DS game *Animal Crossing: Happy Home Designer* (2015).

The Amiibo series was launched in November 2014. It is based on a wireless

communications and storage protocol that connects data stored on branded figurines to the Wii U, Nintendo 3DS, and Nintendo Switch. The Amiibo platform included both toys and trading cards, which used NFC to interact with supported software, allowing data to be transferred into and out of games and shared across multiple platforms. By the end of 2016, Nintendo had sold more than thirty-nine million Amiibo toys and more than thirty million Amiibo cards.

A conventional controller, called the Pro Controller, could also be purchased for the Wii U. The Pro Controller is an updated version of the Wii's Classic Controller that more closely resembles the controllers used by Microsoft and Sony consoles. The Wii U was compatible with existing Wii controllers, and up to four Wii Remotes could be used simultaneously, along with two Wii U GamePads.

The Wii U was originally released in two versions, with either 8 GB or 32 GB of storage. The latter “deluxe” or “premium” console also came with a Nintendo Network Premium subscription and was bundled with the game software *Nintendo Land* (2012).

Nintendo launched a service called Virtual Console in January 2013. The Virtual Console republished selected NES and Super NES titles that could be purchased and played on the Wii U or GamePad. In March 2014, selected Game Boy Advance titles were added, and from April 2015 onward, selected Nintendo 64 and Nintendo DS games were also available for download.

The Wii U further entrenched the dominance of Nintendo’s classic game franchises on Nintendo consoles. Seven of the ten best-selling games were updates of franchises for the Wii U: *New Super Mario Bros. U* (2012), *Super Mario 3D World* (2013), *The Legend of Zelda: The Wind Waker HD* (2013), *New Super Luigi U* (2013), *Mario Kart 8* (2014), *Super Smash Bros. for Wii U* (2014), and *Mario Party 10* (2015). Each game sold over two million copies. Nintendo was also successful in expanding its software’s dominance on the platform with the launch of newly conceived games, such as *Nintendo Land* (2012), *Splatoon* (2015), and *Super Mario Maker* (2015), which were also among the top-selling software for the console.

Online functionality for the Wii U centered around the Nintendo Network platform and the Miiverse, an integrated social networking service that allows users to share content in game-specific communities. The creation of Mii avatars remained an important part of the

Wii U experience, and the Miiverse extended the functionality of the Mii into a social media–like environment. The Miiverse allowed users to share limited forms of communication, including in-game accomplishments, comments, and handwritten notes. Some game software added more functionality through the Miiverse; for example, *Super Mario Maker* allowed users to share comments and feedback on user-created levels.

The Wii U had low sales; just over thirteen million units were sold compared to over one hundred million for the Wii. The key innovation of the Wii U is the additional screen supplied by the GamePad that can be used as a supplement to the main display, or games can be played directly on the GamePad. The Nintendo Switch retained and refined this concept.

Non-Player Characters (NPCs)

A non-player character (NPC), or non-playable character, is a character who is not controlled by the player in a video game. The term *non-player character* comes from the tabletop role-playing game (RPG) *Dungeons & Dragons* (1974), in which NPCs are created and controlled by the game master (GM). These characters are either friendly or unfriendly to the player characters, and a GM must prepare enough information about all NPCs to allow for both scenarios. Just as the GM in *Dungeons & Dragons* controls NPCs based on predetermined characteristics, NPCs in video games are generally controlled by the game's artificial intelligence (AI) system or, as in some massively multiplayer online role-playing games (MMORPGs), by game moderators.

Making NPCs believable to the player through both narration and gameplay is one goal of narrative games. David Freeman lists seven narrative strategies among his thirty-two “emotioneering” techniques, including “techniques which make major NPCs . . . dimensional and

fresh, and thus interesting[.] . . . techniques which give major NPCs emotional depth and complexity . . . ways to make it feel as if major NPCs have an emotionally complex relationship with the player” and “ways to give the player emotionally complex relationships with major NPCs” (Freeman 2004). Petri Lankoski and Staffan Björk address five aspects of NPCs in *The Elder Scrolls IV: Oblivion* (2006) as they are experienced through gameplay: “human body; self-awareness, intentional states, and self impelled actions; expression of emotions; ability to use natural language; and persistent traits” (Lankoski and Björk 2007, 417). Believable NPCs who react to the player can help create a sense of “social presence” in the game world, particularly in single-player games (Nitsche 2008, 205–207). NPCs can function as information sources for players. Suellen Adams discusses the function of NPC “trainers” and “contacts” in *City of Heroes* (2004) as sources of both actively sought and passively received information (Adams 2009, 289).

Although narrative game design sometimes envisions NPCs as playing a similar narrative and identificatory role to characters in other media (print, film, etc.), video game theorists have argued that NPCs should also be studied on the basis of their behavior and functions. For example, Marsha Kinder argues (1991, 107) that the use of former NPC Princess Peach as a playable character in the North American release of *Super Mario Bros. 2* (1988) may lead boys to “risk . . . transgender identification” while playing, shifting the gender dynamics of the game and its players. James Newman argues that during online or participatory gameplay, both playable characters and NPCs are experienced less as

In the prologue to *Final Fantasy IV* (1991), NPC lack of complexity is humorous, as multiple identical soldiers reply to the player with the same dialogue. (Courtesy of Mark J. P. Wolf)

narrative or visual elements than sets of capabilities and actions (Newman 2002).

The presence of NPCs may change the overall structure of a game. Jesper Juul sees NPCs in *EverQuest* (1999) as part of the “embedded progression structures” in a “game of emergence,” describing how NPCs may ask the player to perform certain tasks, leading the player to engage in sequentially progressing “quests” within an otherwise open-ended game (Juul 2002, 328). In NPC-driven narratives, character locations may be marked on the game map so that the player knows where to go if he or she wants to continue that character’s story.

REPETITIVENESS AND ADAPTABILITY

Because there are often many more NPCs than player characters, one aspect of NPCs is their repetitiveness. Different NPCs are often identical in appearance, and they may repeat the same actions and dialogue over and over again. In the single-player RPG *Final Fantasy IV* (1991), characters of the same type (soldiers, dancers, shopkeepers, healers) are all represented by the same avatar, with different clothing and hair colors. Moreover, not only do characters usually repeat the same comments every time the player talks to them, but some NPCs repeat the same dialogue. These limitations of early video game technology become a joke in the prologue to the game. As the player walks around a castle, several identical-looking soldiers seem startled when the player tries to talk to them, saying, “I’m not sleeping!”

Gail Shivel describes NPCs’ repetitiveness as part of *World of Warcraft* (2004), writing, “A non-player character in

Elwynn Forest will always ask you to carry a note to her lover if you have not already done so; a bounty on a gnom named Hogger is collected a hundred times a day on every game server. . . . Every zone and every non-player character has a history—a backstory—and a desired outcome, which is repeated endlessly to every new player who comes along” (Shivel 2009, 211). Robert Yang criticizes this fungibility, arguing that open-world RPGs are often populated by NPCs with “generic identities” understood as “non-crucial actors who are infinitely replaceable by the game” (Yang 2017, 97–99).

Although the Digital Games Research Group at the University of Ulster in Northern Ireland suggests that the adaptation of NPCs over the course of a game is just one strategy for adaptive game design, calling the modification of NPCs “the most obvious way to adapt a game” (Digital Games Research Group 2005, 8), many scholars have proposed artificial intelligence (AI) models to increase NPC adaptiveness in games. In response to NPC repetitiveness in persistent MMORPG game worlds, Kathryn Merrick and Mary Lou Maher suggest the use of motivated reinforcement learning agents, through which NPCs “explore their environment and learn new behaviors in response to interesting experiences” (Merrick and Maher 2007, 127). Brian MacNamee and Pádraig Cunningham propose programming strategies for “Proactive Persistent NPCs[,] . . . NPCs that are always modeled (at least to some extent) even when the human player is not in their vicinity” (MacNamee and Cunningham 2001, 221).

Daniel Johnson and Janet Wiles discuss the advantages and disadvantages

of several different AI systems for the behavior of NPCs, including neural networks and evolutionary algorithms, both of which are models for adaptive AI, and extensible AI, first used in *Quake* (1996), in which the player can control how NPCs react to enemies (Johnson and Wiles 2001). In Bioware's *Dragon Age: Origins* (2009), NPCs can be programmed by the player with Combat Tactics, conditional scripts for character behavior that allowed party members to fight autonomously and in real time. The entire game can be played controlling only the Warden, maintaining all other characters' statuses as NPCs.

BECOMING PLAYABLE CHARACTERS

In many single-player RPGs, characters that the player first encounters as NPCs later enter the player's party, becoming playable characters. In *Final Fantasy VI* (1994), the mercenary Shadow repeatedly enters and leaves the player's party, acting as both a playable character and an NPC. In the third-person shooter *Resident Evil 4* (2005), Ashley Graham, an NPC the player is trying to rescue through most of the narrative, briefly becomes a playable character.

NPCs that are popular with players may go on to become playable characters in future additions to a game franchise. Nintendo has built an extensive cast of playable characters from NPCs in the Mario franchise, allowing for a multi-player racing game (*Super Mario Kart* [1992]), a fighting game (*Super Smash Bros.* [1999]), a sports game (*Mario Tennis* [2000]), and even a board game (*Mario Party* [1998]) incarnations of the series.

NPCs may also become playable characters through expansion packs that coexist in a single game world. Capcom's first expanded version of *Street Fighter II* (1991), *Street Fighter II: Champion Edition* (1992), was virtually identical to *Street Fighter II—The World Warrior* (1991), aside from the addition of the four NPC "bosses" from the earlier game as playable characters. *Grand Theft Auto IV: The Lost and the Damned* (2009) is an episodic expansion pack that centers on the NPC biker gang the Lost from the original *Grand Theft Auto IV*, making their leader, Johnny Klebitz, the new playable character. Playable characters in one iteration of a series may become NPCs in later installments as well, such as when Leliana and Morrigan from *Dragon Age: Origins* become NPC advisers in *Dragon Age: Inquisition* (2014).

In *The Sims* (2000), almost any NPC can become a playable character and vice versa. The player controls only one character at a time while the computer controls other characters, and players can shift player characters within their household at any time or select other households from the neighborhood map. Even maids, firemen, and burglars, who often look identical and do not have houses on the neighborhood map, can become part of the player's family through friendship or marriage, becoming playable characters. One notable exception in the *Sims* franchise is the Grim Reaper, who cannot be dated or married and for the most part cannot join the player's family. The Tombstone of Life and Death cheat in *The Sims 2* (2004) allows a sim to become pregnant by the Grim Reaper, though adding him to a household may permanently corrupt the game.

VALUES AND NPC INTERACTION

Rules for interaction with NPCs conspicuously communicate a game's values (Flanagan and Nissenbaum 2014, 48). Some shooting games, such as Atari's *Area 51* (1995), punish the player with the loss of life or other points for shooting nonenemy NPCs. In Nintendo's *The Legend of Zelda* franchise, if a player attacks harmless chickens too many times in a row, a swarm of chickens appears and begins attacking the player. Rockstar's *Grand Theft Auto* franchise allows players to collect money by killing innocent NPCs; however, if there are police in the area, they will begin chasing the player. Some games reward gendered violence against NPCs, as in the "Dastardly" achievement in Rockstar Games' *Red Dead Redemption* (2010) and the "Gender Wars" power-up for the dark-skinned character Purna, who is framed in Techland's game *Dead Island* (2011) as "man-hating" (Yang 2017, 100–106).

NPC interactions may help players think through ethical decision making, as in *BioShock* (2007), which presents the player the choice of whether to rescue or "harvest" the childlike Little Sisters in Rapture. The plot of *Undertale* (2015) also hinges on the player's choice to kill or spare NPCs, with its "pacifist" and "genocide" routes shifting the player's relationship to all NPCs in the game. LV and EXP, stats earned for killing NPCs in many RPGs, are termed Level of Violence and Execution Points in *Undertale*'s game world.

Nicholas Ware argues that the iterative quality of romance and dating mechanics in games produces "video games' Nice Guy Syndrome" (Ware 2015, 225). In playable (not scripted) romance and sex scenes with NPCs, players are

encouraged to learn an NPC's preferences and cater to it to win affection, with sex as a "reward" for correct choices (Ware 2015, 227). In farming simulator games such as the *Harvest Moon/Story of Seasons* series and *Stardew Valley* (2016), giving appropriate gifts is the primary mode of interaction with NPCs as well as the primary dating mechanic.

Games in the dating simulator or visual novel genre may engage in metacommentary on the player's dates with NPCs: *Dream Daddy: A Dad Dating Simulator* (2017) gives letter grades to each date in colorful intertitles. Successfully dating all NPCs in a game may reveal new narrative information, as in PigeoNation's *Hatoful Boyfriend: A School of Hope and White Wings* (2011). NPCs in visual novels may also break the fourth wall, showing their awareness of the game's own dating mechanics, as in Cheritz's *Mystic Messenger* (2016) and Team Salvato's *Doki Doki Literature Club* (2017). These characters' self-awareness challenges the player's feeling of control in NPC dating situations and shows the developers' understanding of the limitations of romance between players and NPCs.

North America. See Canada; Mexico; United States of America

Norway

Norway is a country of about five million inhabitants, and it is known for its high penetration and early adoption of technologies. Around 35 percent of Norwegian citizens play video games on a daily basis, and for children between ages nine and eighteen, 77 percent of the boys and 47 percent of the girls report playing games on a computer, game console, smartphone, or tablet daily.

Although Norway was an early adapter of the new computing technology for research purposes in the 1950s, professional game development emerged late in Norway. As home computers were domesticized in the late 1970s and 1980s, the Commodore 64 and Amiga 500 were particularly popular in Norway. These technologies were important for why Norway had a vibrant demoscene culture in the 1980s and 1990s. The demoscene was a subculture originating in the home computer culture related to the 1980s software piracy scene but which also developed into a creative art form of its own. Early experimentation with game development took place in the demoscene, and while most of it remained a hobbyist endeavor, there are examples of game projects that eventually were released, such as *Fuzzball* (1991), developed by Scangames Norway, a company that sprang out of the demoscene group Razor 1911.

The first attempts at creating businesses around game development can be traced to the early 1990s, although up until around 2010, game development in Norway centered around one international triple-A developer, Funcom, and a handful of smaller companies focused on serious games for a domestic market that ranged from advergames and children's games to training simulations for the petroleum industry. Funcom originated as a third-party developer of games for consoles such as the Super Nintendo Entertainment System (SNES), SEGA Genesis, and the Sony PlayStation, but it made an impact with the adventure game *The Longest Journey* (1999) based on its own IP. Later, it became known for specializing in massively multiplayer online role-playing games (MMORPGs) such as

Anarchy Online (2001), *The Secret World* (2012), and *Age of Conan* (2008). Another example of a still operational Norwegian game company that emerged in the 1990s is Ravn Studio, which has focused on children's games based on Norwegian franchises, such as *Flåklypa Grand Prix* (2001–19), *City of Friends* (2011–14), and *Captain Sabertooth* (2011–16). They have also released games based on their own original IP, such as *Angel Adventure* (2008–16) and *Snakeball* (2007).

With the emergence of new distribution solutions, networked society, and smartphone technology, game development has come to be viewed as an attractive new industry for game enthusiasts, and since 2013, the Norwegian game industry has counted around one hundred small and medium-sized game development companies. Most Norwegian game companies are today independent of external ownership and constraining publisher agreements; they seek investor money and support from private and semiprivate funds. Some also develop games by contract, and having parallel activities to fund game development is not uncommon. Some of the most successful companies who have emerged in this period are Playfish, a game company that focused on games for Facebook and social networks and was acquired by Electronic Arts (EA) in 2013 for \$400 million, and Dirtybit, an independent company with one hundred million downloads of their mobile franchise *Fun Run* (2012–18). Some companies have also emerged as former Funcom employees have branched out and started their own businesses. Megapop (*Trolls v. Vikings* [2014]) and Snowcastle Games (*Earthlock* [2018]) are examples of such companies. With its international hit

Wordfeud (2010) for smartphones, Bertheussen IT is also one of the most successful Norwegian game developers.

The emergence of a Norwegian game industry should be viewed in the context of the establishment of a public cultural policy for game development, reflecting traditional welfare state measures meant to positively influence the culture and media sector by protecting it against market forces and global mass culture. The introduction of a cultural support scheme for game development was initiated in 2003 as a response to the influx of violent video games from abroad and was proposed as a cultural policy that would secure children's access to nonviolent video games with Norwegian language and content. The initiative was followed up by the world's first white paper on video games in 2008. The white paper stressed the cultural importance of securing children's access to diverse, high-quality audiovisual content in the Norwegian language, but it also emphasized the importance of establishing trade measures to strengthen the game industry by creating jobs and fostering a higher innovation rate.

As of 2019, Norway's dedicated funding scheme for game development is administered by the Norwegian Film Institute (NFI), which historically has been the state agency for film funds. Game developers can apply for support for 75 percent of the production costs or 50 percent of the costs for marketing/launch of games that foster Norwegian cultural heritage, and there are also options for travel grants and manuscript development grants. Apart from the cultural scheme, Norwegian game developers have also benefited from support

from general innovation grants. While the total amount that Norwegian game developers can receive through support schemes is not enough to cover the typical costs of a triple-A production, the cultural support and the focus on digital distribution and smartphones stresses a focus on small-scale productions on easily accessible platforms with a bias toward Norwegian cultural expressions.

NPCs. See Non-Player Characters

Oculus Rift

Virtual reality (VR) technologies have been of interest for industrial and military purposes since the late 1960s, when Ivan Sutherland and his assistants developed “the Sword of Damocles” head-mounted display (HMD) at Harvard University (Sutherland 1968, 757). Gaming interests were much slower to develop, with the first gaming 3-D/VR head-mounted devices arriving two decades or more after the original HMDs. Devices such as Nintendo’s Famicom 3D (1988) and Virtual Boy (1995), Virtuality Group’s arcade games (early 1990s), and SEGA’s arcade games (mid-1990s) opened up the promises of VR gaming for the consumer market but failed to gain large adoption due to the inability of the hardware to deliver on those promises (Bown et al. 2017, 249–251). These two periods of the initial HMD development and the first adaptations for gaming have been termed the first and second waves of VR, with the third wave beginning with the development of the Oculus devices (Henze and Kunze 2017, 14).

THE THIRD WAVE STARTS WITH OCULUS

In 2009, Palmer Luckey, an employee of the University of Southern California’s Institute for Creative Technologies, developed an HMD using readily available electronics and optics. It used a powerful personal computer to produce

the imagery for the device, which kept the cost of the HMD low, yet it delivered high-quality computer graphics available via sophisticated graphics cards. He decided to call his organization Oculus and the device “the Rift,” as it “creates a rift between the real world and the virtual world, though I have to admit that it is pretty silly” (Luckey 2012a). In 2012, Luckey approached well-known game middleware developers Brendan Iribe, Michael Antonov, and others to lead the newly formed Oculus VR corporation in producing a consumer device.

Luckey shared his early prototype with other VR entrepreneurs, including John Carmack, founder of Id Software, the developer of many highly regarded games that pioneered consumer three-dimensional graphics. Carmack was impressed with the device and demonstrated a modified version at the Electronic Entertainment Expo in 2012. A year later, he joined Oculus VR as chief technology officer (CTO). Prior to this time, Oculus VR had mostly relied on crowdfunding for capital investment, but it began a round of funding under the leadership of the venture capital firm Andreessen Horowitz, which led to a period of stable finances for the company.

In March 2013, the first developer kits shipped, although the initial plan was “to have the developer kits to all our backers before the [2012] holidays” (Luckey 2012b). These first DK1 devices were premiums for the Kickstarter campaign of

2012 for supporters contributing \$300 or more. The DK2 was released in July 2014 to address several technical limitations of the original DK1, with the goal of producing a consumer version of the Rift by the first quarter of 2016.

The major event in the company's history also occurred in 2014: the social media giant Facebook purchased Oculus VR for \$2.3 billion in cash and stock. The CEO of Facebook, Mark Zuckerberg, saw this acquisition as a path to the future for his company, writing, "Oculus has the chance to create the most social platform ever, and change the way we work, play and communicate" (Facebook 2014). Under the aegis of Facebook, Oculus has been able to expand through partnerships and acquisitions. In 2015, it partnered with Samsung to produce the Samsung Gear VR hardware and software, released on November 27, 2015. Acquisition of Surreal Vision in May 2015 bolstered the ability to 3-D map an environment in real time, and the purchase of the Eye Tribe in December 2016 improved the VR experience by making render quality depend on where the user looks. With these acquisitions, Oculus VR was more fully equipped to extend its devices into the areas of augmented and mixed realities that had emerged as more popular, and hence more profitable, than VR.

On May 21, 2014, ZeniMax Media, the parent of game developer Id Software, sued Luckey and Oculus VR for using its intellectual property without proper permission in developing the Oculus Rift product and sought financial damages for contract breach, copyright infringement, and unfair competition. John Carmack and Brendan Iribe were later added to the lawsuit. The jury trial ended on February 2, 2017, with the verdict that

Luckey had violated the nondisclosure agreement (NDA) he had signed with ZeniMax in 2012. The jury awarded \$500 million to ZeniMax (Orland 2017). Significantly, the jury found that none of the defendants (Oculus, Facebook, Luckey, Iribe, and Carmack) misappropriated or stole trade secrets. Oculus VR was ordered to pay \$200 million for breaking the NDA and an additional \$50 million for copyright infringement. Beyond this, Oculus VR and Luckey were ordered to pay \$50 million each, and Iribe's portion was \$150 million. As a result of subsequent appeals, a new judge cut the jury award to \$250 million (plus interest of \$54 million). In December 2018, ZeniMax and Facebook/Oculus VR settled the lawsuit for an undisclosed amount (Stampler 2018).

In tandem with the development of the devices, Oculus began promoting content creation for the device, starting Oculus Studios in 2014 to help third-party studios create games and experiences for the Oculus Rift. As part of this push, they began Oculus Story Studio (OSS), a VR animation studio, naming Saschka Unseld (formerly of Pixar) as creative director (Zeitchik 2015). OSS screened three VR films at the Sundance Film Festival: *Lost* (2015), *Henry* (2016), and *Dear Angelica* (2017). The production side of OSS was closed in May 2017, but the studio continues in existence to promote the three films it produced.

After staying with Oculus for two years after the Facebook acquisition, Palmer Luckey left the company in 2017 due to disagreements with Facebook management. Brendan Iribe also left Oculus in 2018—reportedly over differences with Facebook management concerning the direction that Oculus VR should pursue

in the consumer market—to take “the first real break I’ve taken in over 20 years” (TechCrunch 2018). As of 2019, Carmack has remained CTO and continues to lead the development of new products for Oculus.

OCULUS VR PRODUCTS

Oculus produces several devices for the consumer market and has been at the forefront of the third wave of VR resurgence. The complete technical details for each product briefly discussed here are widely available, so only a concise overview of each device is included in this entry.

Original Prototype

The prototype used a side-by-side stereographic video stream using a 5.6-inch VGA display with a native resolution of 1280-by-800, which meant approximately 640-by-400 for each side. The body was made from laser-cut sheets of plastic that slid together and were secured with small bolts. The display module was meant to be detachable from the optics module to modify, replace, or upgrade the lenses. A version of this was shown at E3 in 2012.

DK1

Oculus chose a 1280-by-800 resolution 7-inch display for the first developer kit, which weighed thirty grams more than the 5.6-inch display of the original prototype. This display beat the prototype in almost every key area, including response time, switching time, contrast, and color quality. The improved switching time of the panel alleviated most of the motion blur in the original prototype. Oculus

also developed its own 9DOF motion sensor to improve performance in VR-critical areas. It supported a refresh rate of up to 1000 Hz, several times faster than the previous sensor. In addition to the accelerometer and gyroscope, it also included a magnetometer, improving sensor data collection and head tracking. Data coming from the new sensor could be accessed using the Oculus SDK (in easy to manipulate formats such as quaternion, matrix, and Euler angles) or directly as raw sensor data. This version shipped in March 2013 as a premium for those who contributed \$300 (for an assembled kit) or \$275 (for an unassembled one) (Oculus 2012).

DK2

The DK2 made several improvements over the DK1, including a higher-resolution 1920-by-1080 OLED display (adapted from a Samsung Galaxy Note 3 smartphone display). It also has a higher refresh rate than the DK1, better positional tracking, and a cable that separates from the HMD, and it no longer needs the external control box. Oculus started shipping the DK2 in July 2014.

Samsung Gear VR

In partnership with Samsung, Oculus helped develop the Gear VR, an HMD that used a Samsung smartphone both as the display and the processing unit for the content. It was released on November 27, 2015.

Consumer Version 1 (CV1)

The Consumer Version of the Rift is an improvement over the DK2. It features

separate 1080p OLED displays (with a 90 Hz refresh rate) for each eye, 360-degree positional tracking using LEDs in the back of the headset, integrated audio, positional tracking volume, a lower weight, and renewed attention to consumer ergonomics and aesthetics. Positional tracking is accomplished using a sensor system placed within the tracking area that has optical sensors that detect the IR LED markers on the tracked devices (such as the HMD and hand controllers). A business version of the CV1 was announced in June 2017. Oculus originally planned on shipping these in March 2016, but due to a parts shortage, they finally shipped in July 2016. This model is scheduled to cease production sometime in the next year.

Oculus Go

The Go is a stand-alone VR HMD device that involved the cooperation of the mobile chip developer Qualcomm and the Chinese smartphone manufacturer Xiaomi to bring to the market. The device uses Qualcomm's Snapdragon 821 processor instead of a personal computer for processing gameplay. The display is a 5.5-inch LCD with a resolution of 2560-by-1440 (1280-by-1440 per eye) and uses the same Fresnel lenses found in the original Rift. Unlike the Rift, it has just three degrees of freedom in its tracking area, but it includes a small hand controller for VR interactions. Two audio speakers provide spatial surround sound, but the device also includes a 3.5 mm jack for user-provided headphones. Accessories include prescription lenses for insertion into the device. Two storage configurations are available, with 32 GB of internal storage (\$199) or 64 GB of internal storage (\$249).

Oculus Rift S

The Oculus Rift S breaks little new ground vis-à-vis the CV1 model and even backtracks somewhat. Changes include a slower refresh rate (80 Hz) for the single 2560-by-1440 LCD display (which cannot display the deep blacks of the original Rift's OLED displays). Because of these substitutions (which are not necessarily improvements to the device), Oculus calls it *Rift S* and not *Rift 2*. A different approach to tracking uses five cameras onboard the headset: two on the front, one each on the left and right sides, and one looking directly upward. The cameras can be fed directly to the display so that a user may move in the real world without removing the Rift S, which Oculus terms *Passthrough+*. The original Rift's headphones have been replaced by a pair of speakers integrated into the headband, two inches above the user's ears, which is a step backward from the CV1 Rift. In partnership with Lenovo, the Chinese PC manufacturer, Oculus reconfigured the ergonomics of the head straps in a similar fashion to a PlayStation VR HMD. The hand controllers have also been changed to meet the demands of the new onboard tracking cameras, with the ring now appearing on top of the controller rather than below. This new consumer Rift S model shipped May 21, 2019.

Oculus Quest

Originally dubbed the "Santa Cruz" when announced by Mark Zuckerberg in 2016 at Oculus Connect 3, the Quest is much like an uber version of the earlier Oculus Go; it is also a stand-alone VR HMD device, but it uses a more powerful

Qualcomm Snapdragon 835 mobile chip for processing might. It also has two diamond Pentile OLED displays, one for each eye, with individual resolutions of 1440-by-1600 and a refresh rates of 72 Hz. It keeps the same lens technology from the Go, which helps to minimize visual artifacts such as god-rays, and, unusually for Oculus, it also features a physical interpupillary distance adjustment. Like the Rift S, the Quest also shipped on May 21, 2019.

TRACKING HARDWARE AND TOUCH CONTROLLERS

The first sensor system that enabled the tracking of the HMD and hand controllers was named *Constellation* by Oculus VR. It has optical sensors that detect the IR LED markers on the tracked devices as they blink in specific patterns. Recognizing the configuration and pattern of the blinking LEDs on a device allows the system to determine its precise position with great precision and almost no latency. One or more USB infrared sensors (which can be mounted on walls or ceilings or set on stands) provide the system with depth information about the area. The Constellation system was dropped in the later Rift models for an onboard-the-HMD camera system, which solved some of the early tracking problems.

Early Oculus Rift units came with an Xbox One controller for convenience in navigating and interacting with the games available for the device. By mid-2016, Oculus had developed its own controllers for the Rift, called the *Oculus Touch*. The Touch consisted of two hand-held units, each with an analog stick, three buttons, and two triggers (one for

grab and the other for attack). The x, y, and z coordinates of the controllers are tracked in the area by the tracking system used by the particular Rift model being employed. The Touch was originally an accessory for the Rift, requiring a separate purchase, but finally, in August 2017, the Oculus Touch and a second tracking sensor were added to the standard Rift bundle.

GAMES FOR THE OCULUS HMDS

Palmer Luckey's reason for developing the Rift was almost exclusively to play games. Although the Facebook acquisition broadened that emphasis to include industrial, communication, and social foci, by and large, most of the usage for an Oculus device is to play games. Over the course of time, several games have emerged that have played an important role in the history of the Rift. The short exploration that follows covers some of them.

DOOM BFG

This game was the original demo by John Carmack at E3 in 2012. It was supposed to have been bundled with the DK1 when it shipped, but it was not ready yet and was never subsequently released for Oculus. However, an Oculus port of *DOOM 3* (2004) exists.

EVE Valkyrie

CPP games created *EVE Valkyrie* in 2015 based on its massive multiplayer online game (MMO) *EVE Online* (2003). It was bundled with the consumer version of the Rift in 2016. At the time, Palmer Luckey said,

EVE: Valkyrie is one of the most anticipated virtual reality games, and one of the first true VR games to go into development. It perfectly captures the promise of immersive gaming, shooting you into a sci-fi adventure as you pilot a spaceship in search of combat. Battling your friends (and enemies) in multiplayer space dog-fights is the ultimate VR thrill, and we're excited to partner with CCP to bring this experience to Rift owners everywhere. (Morrison 2015).

Beat Saber

Beat Saber, a popular game made for Oculus Rift devices, is typically included on lists of best Rift games and was an included launch title for the Oculus Quest in May 2019. The player slashes colored blocks while avoiding mines and walls, all of them approaching in 3-D space. *Beat Saber* became the highest-rated game on Steam less than a week after its release.

Moss

Polyarc Games released *Moss* to several VR platforms in 2018. It throws the player into a fantasy world of anthropomorphized animals working to defeat a villainous snake, mainly through solving puzzles. It is routinely rated as one of the best VR games.

The Elder Scrolls V: Skyrim VR

Bethesda's masterpiece role-playing game (RPG) was eventually released for Oculus Rift. *Skyrim VR* is the full *Skyrim* experience, explorable with even more immersion, and an excellent example of a port from a traditional gaming

experience to a very high-quality VR one that tops the original.

Online Games

As the term *online* refers to the phone- and data-line connections through which

networked computers communicate, *online games* refers to those video games that can be found and played on networked computers or computing devices and on the internet, including its graphical interface, the World Wide Web. Used even more loosely, the term *online games* could apply to games on cell phones and other forms of mobile games that also use telephone technology and connectivity to link players and games. Online games are typically multiplayer games because the reason for being online is usually to allow multiple players at different locations to play together in the same game or game world.

The earliest games to appear "online" were the mainframe games that were accessed remotely from computer terminals during the 1970s. These were typically only available on college campuses and in research laboratories and allowed only a small number of players. As microcomputer technology grew and home computers helped to decentralize computing power, ways of connecting personal computers via telephone lines and modems resulted in the rise of bulletin board systems (BBSs) and networked games, some of which contained games that players could log into and play, although generally no more than about sixteen players could play simultaneously, as in, for example, *Scepter of Goth* (1983). These developed around the same time as multiuser domains (MUDs), and both types of online activities grew throughout the 1980s and helped to shape the massively multiplayer online role-playing games (MMORPGs) that would develop in the mid-1990s.

Home video game console systems first extended to the online world with the release of Mattel's PlayCable service in

1981 and, two years later, the CVC Game-line, a device that plugged into the cartridge bay on the Atari VCS 2600 and a phone jack that allowed games to be downloaded and played but required a subscription to the service. The games, however, were not played online, and it would not be until the release of the SEGA Dreamcast in 1998 in Japan (1999 in North America) that a home console came equipped with a built-in modem that allowed for internet capabilities.

Since the appearance of the World Wide Web in 1993, web-based games have grown in number and popularity, both on personal computers as well as other devices, such as cell phones, iPods, and iPads used for mobile gaming. The ability to play games online has also led to the production of advergames, which are used to advertise products in a way that engages the user, and games designed for use with social media, such as *FarmVille* (2009) and *Mafia Wars* (2009). With the growth of cloud computing, an increasing number of games can be leased online instead of purchased. As digital distribution and downloadable content (DLC) and the bandwidth of home internet connections continue to expand, with all major home consoles and computers featuring a built-in online connection, online games could now arguably be considered the dominant form of gaming.

Ontology

The most common understanding of *ontology* in philosophy is that it is a study of “what there is”—a map of all existing entities (Hofweber 2018). Ontology does not typically end with a sheer inventory of entities but tries to group them into types by describing their general features as well as the relations between them. This often results in conceptual frameworks, typologies, and hierarchies. *Game ontology* can be understood simply as ontology narrowed down to one specific domain—games. Thus, instead of asking about everything that exists, game researchers ask questions about all existing games, their most general features, and the relations between them. In this sense, *game ontology* can be likened to how *ontology* is typically understood in computer science, where it refers to the ontology of very specific local domains, such as object types discerned in particular programming languages or operating systems.

Similarly to general ontology, game ontology is very often closely connected to language. There are three reasons for this. First, the discovery of the general features of games is often conducted via conceptual analysis, that is, the study of meanings and usage of words. Second, conceptual frameworks created by game ontologists can be treated as new

languages for game description (Zagal et al. 2007). Third, ontological analyses can serve as a basis of new definitions of key concepts such as *game*, *mechanics*, and *immersion*.

Apart from being an autonomous discipline, game ontology can also be used to detect ontological assumptions of existing game research and show how these assumptions codetermine the author's claims. In addition to that, it is very common for papers belonging to other subfields of game studies to contain an ontological section in which the authors adhere to general fundamental properties of studied phenomena to better define the subject of their research.

FOUR TYPES OF GAME ONTOLOGY

Researchers who study general features of games may look at their subject from at least four perspectives that differ in scope.

First, they may be asking *external* questions and wonder how games and their elements should be located on the general ontological map—how they relate to other types of objects. For example, they may ask whether games should be treated as fictional (Tavinor 2017), virtual (Aarseth 2007; Chalmers 2017), or possible objects (Van Looy 2005) or investigate how games relate to other media (Ziegfeld 1989; Ecenbarger 2016). They may try to locate games within existing ontological categories (such as objects or processes [Aarseth 2014]) or postulate completely new general ontological categories suitable for the description of games, such as “unit operations” (Bogost 2008).

Second, game ontologists may employ a more *internal* perspective—focusing exclusively on games and trying to describe their most salient properties and parts. This study could result in a suggestion of a new definition of *games* (Arjoranta 2014; Stenros 2017), a description of their common internal structure (e.g., a division between their ludic and narrative side [Juul 2005], or the establishment of a general typology of games [Cailliois 1958; Carter et al. 2012]).

Third, researchers can focus on a given subset of games and try to establish its unique identity. One popular example of this approach is the study of particular game genres (Karhulahti 2011), but the grouping of games does not have to conform to typical genre divisions (Chia-pello 2013; Garda and Grabarczyk 2016).

Last but not least, game ontology can sometimes concentrate on particular properties or parts of games and try to describe them in a general manner or supply a framework for their categorization. Some of these aspects have their counterparts in the considerations from general ontology. Discussions on space (Fernández-Vara et al. 2005) and time (Zagal and Mateas 2007), the status of rules (Juul 2005; DeLeon 2013), agency (Nguyen 2019), or emergence (Juul 2002) can serve as examples. In other cases, game scholars focus on aspects unique to games, such as mechanics (Sicart 2008), immersion (Calleja 2011), quests (Aarseth 2005), or avatars (Klevjer 2006).

Focusing on game elements does not keep the resulting frameworks from being comprehensive. Two good examples of such bottom-up overarching projects are the Game Ontology Project (<https://www.gameontology.com/index>

.php/Main_Page) and the Historical-Analytical Comparative System (HACS) (Therrien 2017). In both cases, the sheer number of recognized and categorized game elements enables their authors to develop frameworks that are universal enough to describe most existing games. Description and categorization of game elements bring game ontology close to some of the approaches to game design that may contain their own ontological descriptions.

META-ONTOLOGY: HOW IS GAME ONTOLOGY EVEN POSSIBLE?

On the face of it, developing ontology for the domain of games may seem like a futile task. Games are artifacts (as opposed to natural kinds), which means that finding stable patterns in their structure or their essential properties may not be possible. The set of *all games* may be simply too heterogenous, as that depends only on the whim of the creators and the players. How can researchers create sustainable categorizations or definitions if the subject of their theories can evolve at any time without any constraints? What is the use of a definition if developers can render it obsolete by creating a game designed specifically to challenge it? The answer to these questions belongs to *meta-ontology*, that is, to the study of methods and aims of ontology (meta-ontology is typically treated as a part of ontology in the widest sense [Hofweber 2018]). There are at least three strategies that game ontologists could employ to solve this problem.

First, game ontologists could focus only on the formal, structural aspects of games (independent from the intentions

of the creators and the interpretation of the users) and map the whole possibility space that these formal properties allow (Aarseth et al. 2003). This results in a fairly foolproof analysis because it gives the researcher a chance to transcend the existing sample of games and talk about any combination of discerned properties (ideally, all possible games).

Second, instead of studying games, researchers may shift their attention to the existing processes of human classification. Instead of discovering what a game or a given genre is, they may try to discover what it is considered to be in a given community. This question can be answered via conceptual analysis or empirical methods, for example, by analysis of the corpus of game descriptions created by the users (Ryan et al. 2015) or journalists (Therrien 2017).

Third, a game ontologist could employ a fully pragmatic attitude. According to this standpoint, game ontology frameworks are simply formal tools that facilitate understanding of games by abstracting away some of their properties. They are models of our game descriptions. Their usefulness is always tied to a task at hand; they may be enough for a given research project, but they do not pretend to capture universal regularities applicable in every case (Aarseth and Grabarczyk 2018). In this sense, the task of the ontologist is similar to the task of a logician creating formal representations of parts of natural languages: it is always possible to represent language in several ways, and the choice between formalizations only depends on how useful they are in a given case.

Open-Source Software

The relationship between video games and open forms of content generation has always been intertwined due to the status of games as playful software systems. *Open-source software* is commonly defined as a mode of production where the source code is open to anyone for modification, regardless of their professional status. Through sharing, reusing, and modifying software in an open setting, new forms of collectively collaborative content altogether has emerged. As Steven Weber noted in 2002 (2), it is this openly collaborative environment that allows for “complex, sophisticated software systems outside the boundaries of a corporate structure and for no direct monetary compensation” to arise. For Weber, examples of open-source software included operating systems such as Linux and web browsers such as Apache (or later Firefox) that presented an alternative to the political economy of commercial media production. However,

with the growth of the internet and its vast variety of participatory cultures, the openly collaborative ethos of open-source software has widened.

The “free-culture movement,” for example, is a social movement aimed at widening the open-source ethos to any creative work by removing copyright concerns (Lessig 2004, 2008). As an industry, video games have always been at the forefront of responding to movements such as free culture, as many games promote participatory activities, such as modding (Dovey and Kennedy 2006, 130). Indeed, many of the most popular game genres were pioneered by nonprofessional modders, many games inspire passionate participatory cultures, and every game is in some sense open due to its status as a played activity. For commercial game developers, promoting these openly co-creative relations is fundamental to the success of their game because participants can lower development costs through playtesting (or participating in early access; see Consalvo and Paul 2017), product life cycles can be extended (Kerr 2017, 93), and games can develop in altogether unpredictable ways. For example, scholars studying modding cultures have noted the way that modders exist in a different “moral economy” to commercial developers, and it allows them to create material not possible in commercial contexts. Mods, which are often illegal due to their precariously copyrighted material, such as a *Game of Thrones* mod in Paradox Development Studio’s *Crusader Kings II* (2012) or a mod of Bioware’s *Mass Effect* (2007) in Firaxis Games’ *Civilization V* (2010), are nonetheless often implemented into the co-creative identity and ongoing economic value of digital games (Postigo 2008; Johnson 2009). Openly

participatory activities, such as those of modders, exemplify the blurred boundaries “between play and production, between work and leisure, and between media consumption and media production” that many game studies scholars have noted (Pearce 2006, 18).

It is beyond the scope of this entry to consider the variety of open-source software present in games due to its sheer ubiquity. What is noteworthy, though, is the synergy between games and their status as an openly participatory and playful activity. As T. L. Taylor notes, the open structure of games poses important questions surrounding the ownership, governance, and ongoing control of a game’s rules (Taylor 2007, 114).

Oregon Trail, The

The Oregon Trail is an enduringly popular series of educational computer games originally imagined as a board game by Carleton College student Don Rawitsch, who was convinced by his roommates, Bill Heinemann and Paul Dillenger, to produce a text-based strategy computer game on teletype, instead of designing a board game, in 1971 (Lipinski 2013). The Minnesota Educational Computing Consortium soon worked to publish the game, releasing it in 1974. The game franchise, designed to teach middle school children about the challenges faced by nineteenth-century pioneers on the Oregon Trail, was meant to ignite students' interest in American history, particularly units on the westward expansion of the mid-nineteenth century.

Today, *The Oregon Trail* refers to a much wider universe of *The Oregon Trail* computer games, retrogames, video games, and card games. (Pressman Toy Corporation released its first *The Oregon*

Trail card game in 2016 and the sequel, *The Oregon Trail: Hunt for Food Card Game*, in 2017.) Pressman also produces the board game *The Oregon Trail: Journey to Willamette Valley* (2018), while also fostering a nostalgic fandom evidenced by listicles (*Buzzfeed's* 2013 listicle "21 Ways *The Oregon Trail* Traumatized You as a Child"), T-shirts, books, and gimmicky travel promotions (Auber 2017; Reeves 2018). Coming full circle, in 2018, Houghton Mifflin Harcourt published a boxed set of paperback history books for young readers based on *The Oregon Trail*. The books, written with clear goals and choose-your-own-adventure narrative options, put the computer game back into the written format Rawitsch, Heinemann, and Dillenger once worked around.

The Oregon Trail's biggest distribution push came when the Minnesota Educational Computing Consortium (MECC) took the original paper teletype code that the three Carleton student teachers had written in 1971. MECC was looking for educational software, and *The Oregon Trail* was a working educational game. Once MECC expressed interest, Rawitsch revised the game to make its historical narrative more complex and accurate (Lipinski 2013). Multiple iterations of the game followed and kept pace with developments in computer and video game graphics and styles. In particular, versions of *The Oregon Trail* produced for the Apple II and other Apple systems are the ones most widely played and remembered by children educated in the United States in the 1980s, when Apple put considerable resources into the education market. The 1985 game, the first graphic edition of *The Oregon Trail*, has a points system and includes

The start screen for one version of *The Oregon Trail*. New versions of the game have appeared since it first came out in 1971. (Courtesy of Mark J. P. Wolf)

weather simulations and other features. One popular gameplay element was that players died (frequently and due to a range of illnesses and disasters and as a result of poor resource management). Upon the death of the player or a member of the player's party, a tombstone scene would play.

But the item that is perhaps the best indication of how deeply and nostalgically adored *The Oregon Trail* universe has become is the 2018 retro handheld game *The Oregon Trail*, which has a complete 1980s graphical version of the game and is designed to mimic the beige case and look of a 1980s computer one might encounter in the school lab. For the generations of former middle schoolers, seeing an electronic screen display "You have died of dysentery" is not just

a momentary textual encounter with nineteenth-century ailments, it is a reminder of educational childhood fun. This nostalgic sheen is important to the continued success and circulation of *The Oregon Trail*'s interface and narrative content: the game's westward migration, pioneer fortitude, and the dangers of nature and poor planning as part of the strategic play involves provisioning and planning that allowed players to virtually travel from Independence, Missouri, to the Willamette Valley in Oregon. Like another popular text produced in the same era, such as the televisual adaptation of Laura Ingalls Wilder's *Little House on the Prairie* series (the TV series airing from 1974–82), these texts simplify, stereotype, and gloss over encounters and tensions with native peoples to

depict the westward migration of white settlers (Landry 2017); *Deadwood* (2004–6) it is not.

In 2011, a fortieth anniversary edition of *The Oregon Trail* was released as a single-player simulation game for the Nintendo Wii and Nintendo 3DS. Between 1975 and 2011, seventeen versions of *The Oregon Trail* were released for platforms that ranged from the Control Data Corporation's Cyber 70 mainframe supercomputer to the Apple II, Commodore 64, DOS, Windows, Macintosh, and more, making it one of the most enduring computer games ever and undoubtedly the most enduring educational computer game to date.

Outsourcing

Outsourcing is when one company hires another company to complete a particular job rather than having it done internally. This may occur for multiple reasons, for example, because the outside company can do the work more cheaply, more quickly, or because they have the experience or expertise that the job in question requires, or it may be that the company doing the outsourcing has enough work already and prefers to outsource the rest rather than hiring more employees. All of these reasons can be found in the outsourcing done in the video game industry.

In the earliest days of video game development, a single programmer was responsible for programming the entire game; for example, many Atari VCS 2600 cartridges were programmed by individual programmers. As games grew in size and complexity, work was divided between team members, but some types of work, such as music, sound effects, and

game character dialogue, were outsourced because production companies did not have in-house composers and voice actors (graphical assets, such as artwork and CG model making, are also sometimes outsourced). Likewise, technical work such as the production of motion capture data was outsourced to companies that had all the required technology and cost less to hire out than to produce in-house. Some types of video game work are more likely to be outsourced, such as the making of ports (other versions of a game) for systems other than the original one (or ones) for which a game was written or the localization of games to fit them into the local culture of a foreign country where a game is being released (see Localization).

By 2009, around 86 percent of game studios were using outsourcing for some aspect of game development (Game Developer Research 2009). Today, collaborations, company acquisition and ownership, branch office locations, and franchised intellectual property (IP) are crossing national boundaries more than ever before, making outsourcing very common. For example, the LEGO Group, a Danish company, hired Travellers' Tales, a British company that is now a subsidiary of the American Company Warner Bros. Interactive (itself owned by conglomerate Time Warner, Inc.), to produce LEGO-themed video games, and to do so, Traveller's Tales outsourced some of the work to the Argentine company Three Melons; the games were then programmed for systems from the United States and Japan; thus, the companies influencing the final form of the LEGO games are located in at least five countries on four continents.

Some game publishers are even wondering whether the video game industry will eventually move to a complete outsourcing model, as is found in other industries, such as motion picture production, where dozens of companies can provide work for a single feature film (Dring 2018). Whatever direction the industry takes, it seems outsourcing will remain an important and common practice.

OUYA

The OUYA is a small Android-based video game console that was the result of a Kickstarter campaign begun by Julie Uhrman in 2012 that raised \$8.5 million for the system (the first million of which was raised in the first day of the campaign). The OUYA was released to donors and later to the public in 2013, retailing for \$99. Every OUYA console is also a developer's kit, encouraging all

OUYA owners to become game developers. As the projects' creators stated, "We're handing the reins over to the developer with only one condition: at least some gameplay has to be free. . . . Developers can offer a free demo with a full-game upgrade, in-game items or powers, or ask you to subscribe."

The OUYA features an Nvidia Tegra3 quad-core processor and has 1 GB RAM and 8 GB of internal flash storage, with an HDMI connection and support for up to 1080p HD. It has wireless controllers with standard controls (two analog sticks, D-pad, eight action buttons, and a system button) and a touchpad.

In January 2015, e-commerce Chinese conglomerate Alibaba Group Holding Limited invested \$10 million in OUYA to integrate the system's software and games into its own set-top boxes. Despite the investment, the OUYA suffered from relatively weak sales to the public, and the company was put up for sale in April 2015. In July 2015, esports pioneer Razer Inc. acquired OUYA's content library and hired some of the company's staff, both of which were used to develop Razer's own Forge TV microconsole, which was later discontinued in 2016.

Razer shut down OUYA's servers on June 25, 2019, making many of the games unavailable, including those requiring a purchase validation when they are launched. Only games downloaded into the systems will remain. Members of the OUYA community raced to download and preserve as many games as they could before the shutdown (Carpenter 2019). As of June 2019, there were 1,250 games available for the OUYA. Though the system has been discontinued, the OUYA community remains active in

online forums, and the system can still be purchased on eBay.

Overwatch

Overwatch (2016) is a competitive first-person shooter (FPS) published by Activision Blizzard. Set on a near future version of Earth, *Overwatch* is primarily played by two opposing teams of six in a variety of familiar competitive modes, including King of the Hill (called "Control" in-game), Capture the Flag, and Escort. Drawing inspiration from class-based shooters such as *Team Fortress II* (2007) and multiplayer online battle arenas (MOBAs) such as *League of Legends* (2009), *Overwatch*'s characters—called Heroes—have highly individuated skill kits that contain several abilities with both short cooldowns and an "Ultimate" ability with a longer one. While Blizzard eschewed a free-to-play (F2P) monetization system in favor of a more

traditional, upfront sale, *Overwatch* players may purchase cosmetic skins and victory poses for their characters using a “loot box” system in which purchased chests randomly distribute in-game items.

While much of its development history is unclear, *Overwatch* is widely thought to have been salvaged from the wreckage of Activision Blizzard’s failed next-generation massively multiplayer online role-playing game (MMORPG) *Project Titan*, which was in development from the late 2000s until 2014 (Schreier 2016). Shortly after the announcement of *Project Titan*’s cancellation in 2014, Activision Blizzard revealed that *Overwatch* would be the company’s first new franchise in nearly two decades. A small development team reportedly reused a number of assets taken from *Titan*’s competitive multiplayer mode to develop a prototype for a class-based, FPS that later became *Overwatch*.

Upon its release in May 2016, *Overwatch* received both critical and commercial acclaim, winning multiple end-of-year awards and gathering an estimated seventeen million monthly active users in its first year (Carpenter 2017a). In addition to attracting a massive number of players, *Overwatch* gave rise to a vibrant participatory culture in which fans created a striking variety of cosplays, unofficial art, and fan fiction based on *Overwatch*’s cast of characters. (For a time, “Overwatch” was among the most searched terms on a number of pornographic databases [Carpenter 2017b].) *Overwatch* was also noted for its popularity among female and LGBTQ+ persons and communities (Riendeau

2016). Despite that fact (or, perhaps, because of it), *Overwatch* sat at the center of a number of controversies around representation and gaming culture. For example, an official holiday comic for *Overwatch* revealed that Tracer, one of the game’s most iconic characters, was in a same-sex relationship. While many celebrated Activision Blizzard’s inclusion of openly queer characters, others felt that the comic had improperly “politicized” the game. The terms of this debate speak to the tensions that were becoming palpable in *Overwatch*’s fanbase. For many, *Overwatch* was as much a culture built around a compelling universe as it was a competitive game to be mastered.

Overwatch’s most enduring legacy, however, is likely the esports product it spawned, the Overwatch League, which held its first season in 2018. In the wake of *Overwatch*’s release, many third-party tournament organizers began to develop a modest competitive circuit for *Overwatch*, as they had long done for Blizzard’s games. But in November 2016, Activision Blizzard announced its intention to create a permanent, proprietary tournament, Overwatch League, that would be modeled on traditional sports (Szymborski 2016). This design choice was notable for two reasons: first, because, excepting the short-lived Championship Gaming Series for *Counter-Strike* (2000) in the mid-2000s, Overwatch League was the first esports tournament to “geolocate” teams in specific cities (e.g., the Atlanta Reign and Shanghai Dragons) and host “home” and “away” matches, as in many traditional sports leagues, and, second, because Overwatch League, along with the League Championship Series, introduced

franchising to esports. Prior to Overwatch League, different esports generally took the form of decentralized “open circuit” ecosystems (similar to professional tennis) or relegation-style leagues (like many European football leagues).

By modeling itself after franchised leagues popular in traditional sports, the design of Overwatch League was intended to create a long-awaited bridge between the game industry and the sports industry, which had long regarded esports with interest but had yet to invest at scale. As Jonathan Kraft, CEO of the Kraft Group, which owns the New England Patriots, told ESPN, “Everybody [in traditional sports] looked at [Overwatch League] and was excited. They saw what we had seen, which is the marriage of the traditional organized league model, with teams in geographies, so cleaning up some of the Wild West nature [of esports], but doing it with a game that was inspiring lots of passion and interest from young people” (Darcy and Wolf 2018). In the end, a number of sports franchises, along with venture capital firms and communications conglomerates, purchased a total twelve slots for a reported \$20 million each. The success of Overwatch League has pushed game publishers to develop new franchising tournaments, such as the Call of Duty World League.

P

Packaging

Video game packaging serves to promote and advertise games in retail stores by attempting to draw the consumer's attention and entice potential players to purchase the game. Early video game packaging often featured artistic conceptions of the gameplay of the packaged games or the themes suggested by the game's title or its play mechanics, sometimes resulting in imagery that had little to do with the game itself or its graphics. The packaging for two games for the Atari VCS 2600 demonstrates this range of representational fidelity to the games themselves: while the box art for Activision's *Pitfall* (1982) depicts a cartoon approximation of the game's core elements and screen, the packaging for *Warlords* (1981) features a painting of a catapult and a medieval knight swinging a sword—quite removed from the gameplay, which involves the player rotating a shield around a collection of blocks in a corner of the screen for protection from the attacks of other players. Although more contemporary packaging still uses artistic renderings of the games themselves, screenshots of a game's graphics and covers that feature these elements more prominently are far more common, in part because of the dramatic improvements in the quality of video game graphics.

Packaging for video games varies between console-based games and home computer games. The packaging for

video games made for console systems is often regulated into specific design templates by the console manufacturer for the purposes of uniformity and product recognition. For instance, almost all games made for the Microsoft Xbox One console are sold in a green plastic case with a clear prominent identifier on the upper part of the front cover trim and at the top of the spine that identifies the game as an Xbox One title. Likewise, games made for the Sony PlayStation 4 and the Nintendo Switch feature similarly distinctive packaging. Packaging for computer games has historically been less restricted, resulting in more elaborate retail boxes and packaging materials; for instance, text game developer Infocom often included supplemental material with its games and featured distinctive packaging, such as the round plastic disc encasement for *Starcross* (1982) and a plastic mask in the front of the original box for *Suspended* (1983).

Video game packaging generally consists of a retail box that contains the game cartridge or disc, sometimes in its own protective case; game manuals; and supplemental information, such as maps and reference cards for game controls. Packaging for consoles may also include materials specific to that system, such as the translucent screen overlays included for games for the GCE/Milton Bradley Vectrex system or the plastic overlays used for the controllers of the Mattel Intellivision system.

Electronic Arts (EA) founder Trip Hawkins helped initiate the use of distinctive packaging with his company's first game releases in the early 1980s. Hawkins saw the marketing limitations of the labeled plastic bags in which many computer games were then sold and instead sold EA games in professionally designed custom packaging more akin to the professional packaging found in the music industry.

More elaborate packaging may be found in limited edition, or collector's, versions of games, which feature supplemental materials or unique elements; these special editions of games have grown more elaborate over time, including items such as maps, figurines, sound-track CDs, supplemental game content, and more. The "Collector's Version" of the Nintendo 64 game *The Legend of Zelda: The Ocarina of Time* (1998) features a gold cartridge instead of the usual gray color, and Microsoft released three different versions of *Halo 3* (2007): the standard version; the "Limited Edition," which was in a metal case and included a supplemental book and disc of bonus materials; and the "Legendary Edition," which included more supplemental disc material and a scaled plastic replica of the main character's helmet for the disc case. Similarly, four versions of *Call of Duty: Modern Warfare 2* (2009) were released, with the most expensive, the "Prestige Edition," including a set of functional night vision goggles. Such limited edition packaging or content is occasionally linked to the prepurchase of games with specific retail stores, to encourage consumers to pay for a portion of an anticipated game before its release to "reserve" a copy and thus be rewarded with special content.

Because packaging for video games typically involves a box that is considerably larger than the cartridge or disc the game contains, several companies and industry initiatives have pushed to reduce the amount of packaging involved. Physical copies of games increasingly include minimal content beyond the game software itself, with even instruction manuals being abandoned in favor of in-game tutorials or digital instructions.

The growth of digital game distribution services such as Valve's Steam, Sony's PlayStation Network, Nintendo Switch Online, or Microsoft's Xbox Live allows games to be sold over the internet, eliminating the necessity for physical game packaging altogether. However, enhanced and collector's editions of digitally distributed games persist and may include supplemental downloadable content, such as digital art books, soundtracks, map packs, additional playable characters or skins, and other similar materials to differentiate the game from a standard edition.

Pac-Man

Sometimes cited as the most popular and most successful arcade game of all time, *Pac-Man* was primarily developed by game designer Toru Iwatani. It was made in eighteen months and was launched by Namco in Japan in 1979 (it was released in 1980 in North America). Initially, the game was titled *Pakku-Man*, meaning the sound of a mouth opening and closing rapidly and continuously. For the Western market, the title was originally supposed to be *Puck-Man*, and it was for European markets. However, for the North American market, Midway, who owned the *Pac-Man* distribution license for the United States, was afraid that players would scratch away at the *P* and change it to an *F*, so the name *Pac-Man* was used instead.

The legend of *Pac-Man*'s origin says that Iwatani's idea for the game came to him when a slice of pizza was removed from a pie, thereby inspiring the iconic shape. According to Iwatani himself, it was in this eureka moment that *Pac-Man* was born; however, he later admitted that the *Pac-Man* figure was also based on the Japanese sign for a mouth combined with eating movements.

The game took the game industry completely by surprise and turned out to be one of the best-selling games ever, taking in more than a billion dollars in revenue. *Pac-Man* has since become an icon of the 1980s and of video games in general. The game's design moved away from the macho themes of its time, showing that it

was possible to make a nonsports and nonshooting game that was compelling and fun, and one that men and women alike would play. *Pac-Man* turned out to be such an enormous success that it was followed with a number of sequels, including *Ms. Pac-Man* (1981), *Super Pac-Man* (1982), *Pac-Man Plus* (1982), *Jr. Pac-Man* (1983), *Pac & Pal* (1983), *Pac-Man & Chomp* (1983), *Professor Pac-Man* (1983), *Pac-Land* (1984), *Pac-Mania* (1987), and *Pac-Man VR* (1996), among others, and many unauthorized clones of the game appeared as well.

The *Pac-Man* character is a yellow circle with a mouth that opens and closes as he moves through a maze, eating dots and getting chased by enemies, referred to as "monsters" or "ghosts" because of their design, each of which has a personal name. In the U.S. version of the game, the red ghost is Blinky, the pink one is Pinky, the cyan one is Inky, and the orange one is Clyde. In Japan, the red one is Oikake (chaser), the pink one is Machibuse (ambusher), the cyan one is Kimagure (fickle), and the orange one is Otoboke (stupid). If *Pac-Man* is caught by one of these ghosts, a life is lost, and when all lives are lost, the game ends.

In each corner of the maze, there is a power-up pill that makes it possible to eat the ghosts and gain more points. When the power-up pill is eaten by *Pac-Man*, the ghosts turn blue for a short time and can be caught by *Pac-Man*. When caught, their eyes return to the starting point at the center of the maze, where they are reborn. When all the dots are eaten, a new level begins.

There are two well-known bugs in the game. A code bug occasionally allows *Pac-Man* to pass through a nonblue

The world's largest *Pac-Man* game, located at the Mall of America in Minnesota. (Thomas Carlson/Dreamstime.com)

ghost without losing a life, and numerous player patterns have been developed to take advantage of this. It stems from problems with the game's collision-detection logic, which goes by tile granularity; if Pac-Man and a ghost switch tiles at the same time, no collision is detected. Another bug is the kill-screen bug at level 256. The level is a dead end, even though *Pac-Man* was originally supposed to be a game with no ending. Consequently, it is not possible to go beyond level 256. On July 3, 1999, the first person to achieve the highest possible score at level 255 (3,333,360 points) was Billy Mitchell from Hollywood, Florida, who completed the game in about six hours.

A Namco Easter egg also appears in *Pac-Man*. To get to it, one has to put the machine into service mode, wait for the settings screen to come into view, and then quickly toggle the service mode off and on. When an alignment grid

appears on-screen, hold down the player 1 and player 2 buttons while toggling service mode on and off again rapidly. If all of this is done correctly, the grid will remain on-screen. Finally, push the joystick up, left, right, and down, four times each, and the message “MADE BY NAMCO” will appear sideways on-screen, spelled out using power-up pills.

Pac-Man's legacy extends far beyond the game itself. First, there are dozens of sequels; according to Mobygames.com, at least forty-four video game versions of *Pac-Man* have been released. *Pac-Man* became such a huge phenomenon in the 1980s that a hit song came out, “Pac-Man Fever,” and it reached No. 9 on the Billboard Hot 100 Chart. *Pac-Man* also spawned an animated television series that ran from 1982 to 1983. Over the years, a wide variety of *Pac-Man*-themed merchandise has also been sold, including clothing, backpacks, school supplies, glasses, board games, playing cards, handheld games, and other toys—even a specially shaped pasta.

The game continues to be ported to an ever-increasing number of new platforms and systems, and thus *Pac-Man* remains a popular game decades after its release; for example, on May 21, 2010, Google changed the Google logo to a *Pac-Man*-like game called *Pac-Man Doodle* for all the users to play.

Pan European Game Information (PEGI) System

The Pan European Game Information (PEGI) system is a European game content rating system that was established to help European parents make informed decisions when buying computer games. The system consists of a rating that indicates suitability by age (3+, 7+, 12+, 16+, or 18+) and content descriptors (Profanity, Discrimination, Drugs, Fear, Sex, Violence, and Gambling) that use easily recognizable icons to identify questionable material. Participation is voluntary for game developers, and to obtain game ratings, a developer completes a questionnaire for evaluating and assigning ratings. In 2015, PEGI added the content descriptor "Online" for games

containing online interactions and, in 2018, "In-Game Purchases" for games containing additional paid content.

PEGI was originally developed by the Interactive Software Federation of Europe (ISFE) and has been in use since April 2003. The PEGI system is based on the Dutch Kijkwijzer system and evaluated in the Netherlands Institute for Classification of Audiovisual Media (NICAM). PEGI is the standard rating system for thirty-eight European countries and Israel. In Portugal and Finland, there have been problems with integrating the system into already existing film classification systems. However, minor age rating adjustments specific to these countries solved the problems.

PEGI is organized into two boards and three committees. The Advisory Board is responsible for making recommendations for the continued updating of the Code of Conduct to ensure that social, legal, and technological developments are reflected in the PEGI system. The Complaints Board deals with any complaints regarding ratings and rating procedures. The Criteria Committee works on adapting and modifying the PEGI questionnaire and the underlying criteria to take into account content, technological developments, and recommendations made by the Advisory Board as well as circumstances brought to light by the Complaints Board. The Legal Committee advises the ISFE of any changes to national legislation within participating countries that could have an impact on the voluntary age rating system. Finally, the Enforcement Committee is charged with implementing the recommendations of the Advisory Board and, more generally, of ensuring the enforcement of the provisions of the PEGI Code of Conduct,

Icons used for the Pan European Game Information (PEGI) game classification system. (Courtesy of Mark J. P. Wolf)

including the conclusions of the Complaints Board.

An addition to the system, PEGI Online, was introduced in June 2007. Any online gameplay service providers that meet the requirements set out in the PEGI Online Safety Code (POSC) earn the right to display the PEGI Online Logo.

Paradox Interactive

Paradox Interactive is a video game publisher in Stockholm, Sweden. Its portfolio includes games developed by its own development branch (Paradox Development Studios) as well as a network of partner developers and subsidiaries that include Obsidian Entertainment (*Pillars of Eternity* [2015] and *Tyranny* [2016]), Colossal Order (*Cities: Skyline* [2015]), Harebrained Schemes (*Battletech* [2018]), and Arrowhead Studios (*Magicka* [2011]). Although its partnership with Obsidian Entertainment demonstrates a willingness to venture into different genres, the company is most readily associated with the particular brand of history-themed strategy games developed by Paradox Development Studios, which combine a fastidious concern for historical realism with "complexity, variety, expandability . . . and the odd technical hitch" (Dean 2013). The company is also notorious for placing a strong emphasis on transparency and

community building. This is evidenced in the manner in which its representatives address the media and other members of the video game industry as well as in the design of its internally developed products, which are characterized by high replayability, mod-friendly features, and abundances of postrelease content; by December 2018, *Europa Universalis IV* (2013) had no less than fifteen expansions to its name.

The history of Paradox Interactive traces back to Target Games, a Swedish tabletop games publisher that was broken up into several separate entities in 1999 after experiencing financial difficulties. One of these entities was Paradox Entertainment, whose business primarily consisted of releasing video game adaptations of popular board games. Over the years 1999 to 2004, Paradox Entertainment used its profits to acquire the rights to lucrative intellectual properties (most notably *Conan the Barbarian* and *Solomon Kane*). As the company's business model transitioned toward licensing, the Paradox Entertainment leadership called upon consultant Fredrik Wester to come up with a business plan for its video game division. Wester saw potential in the team and its assets but failed to impress this idea upon his clients, who elected to close down the division. Sensing an opportunity, Wester bought out the studio, retaining the rights to its previous releases and forming Paradox Interactive.

Although the company primarily remained a developer, Wester's vision always entailed a shift toward publishing. This idea materialized in 2006 when, following poor experiences with publishers, Paradox launched its own online

distribution platform, GamersGate, to answer the demand from countries where traditional distribution methods were ineffective or impractical. Over the next five years, GamersGate gradually expanded its catalog to over three thousand titles, but the breakthrough came in 2011 with the release of *Magicka* (2011), which became the first Paradox-published title to eclipse the one million sales mark. In 2016, Paradox Interactive entered the stock market, which resulted in a massive influx of capital that allowed the Swedish publisher to make several high-profile acquisitions, such as Seattle-based developer Harebrained Schemes, the Swedish role-playing game publisher White Wolf (the *World of Darkness* series and *Vampire: The Masquerade* [1991]), and, in January 2019, the rights to the *Prison Architect* series, formerly owned by Introversion Software.

Historically a PC-focused company, Paradox has made several forays into the console market, with *Cities: Skylines* being ported to consoles in 2017 and Paradox Development Studios' *Stellaris* (2016) being released on consoles in February 2019.

Patent #2,455,992

The first patent for an electronic interactive game was United States Patent #2,455,992, "Cathode-Ray Tube Amusement Device," which was filed on January 25, 1947, and issued on December 14, 1948, to Thomas T. Goldsmith Jr. and Estle Ray Mann. It was for an analog device that controlled the electronic beam of a cathode-ray tube in an interactive fashion (it did not involve a video signal, however, and what it describes could therefore arguably be denied the status of a "video" game). The beginning paragraphs of the patent describe the proposed invention:

This invention relates to a device with which a game can be played. The game is of such a character that it requires care and skill in playing it or operating the device with which the game is played. Skill can be increased with practice and the exercise of care contributes to success.

In carrying out the invention a cathode-ray tube is used upon the face of which the trace of the ray or electron beam can be seen. One or more targets, such as pictures of airplanes, for example,

are placed upon the face of the tube and controls are available to the player so that he can manipulate the trace or position of the beam which is automatically caused to move across the face of the tube. This movement of the beam may be periodic and its repetition rate may be varied. Its path is preferably caused to depart from a straight line so as to require an increased amount of skill and care for success in playing the game.

The game can be made more spectacular, and the interest therein both from the player's and the observer's standpoint can be increased, by making a visible explosion of the cathode-ray beam take place when the target is hit.

After this introductory abstract, the patent goes on to describe the circuitry in detail, referencing diagrams included in the patent. Apparently, the patent's authors did not market or exploit their invention, nor did it appear to be an obstacle to later video game developments.

PC Bangs

A *PC bang* is a South Korean internet cafe that is open twenty-four hours for people to play computer games. It belongs to part of the public room culture, where young Koreans gather to socialize and consume small room entertainment in venues such as video bangs, karaoke bangs, comic book bangs, and so on. The cost of accessing a PC bang is cheap, and the price ranges from 1,000 to 1,500 Korean won (equivalent to USD 1.30) per hour. Users can relax in an air-conditioned room and conveniently order food and drink in their own seats. They can also enjoy playing games with high-speed internet and high-end gaming equipment.

The history of the PC bang dates back to the late 1990s, when the South Korean government developed broadband infrastructure to transform the country's information economy. After the 1997 International Monetary Fund (IMF) financial crisis, some unemployed IT workers set up PC bangs to begin new businesses after they lost jobs in the IT sector. Since then, the PC bang has become an important gaming center that has led to the global rise of Korean gaming culture (Huhh 2007). The vibrant gaming environment in the PC bang contributed to the emergence of early popular titles, including *StarCraft* (1998), *Lineage* (1998), *MapleStory*

(2003), and *Kart Rider* (2004) (Kang 2014). After two decades, the PC bang is still a billion-dollar business. In 2017, the PC bang industry accounted for 1,760 billion Korean won (USD 1.4 billion) in its annual sales. In 2018, over ten million people visited PC bangs in South Korea. The number of PC bangs grew from three thousand in 1998 to more than twenty thousand in the 2000s. Despite the decrease after 2010, the number of PC bangs still remains at 10,418, and their sales revenue increased to 2,334 Korean won (USD 1.9 billion) in 2019.

The significance of the PC bang can be explored in two dimensions. First, the cultural dimension shows that the PC bang shapes the everyday gaming culture in South Korea. Because the home has never been a place for video games in most Korean families, the PC bang is a new “home” for young gamers to visit after school (Shim, Kim, and Martin 2008). The numerous tournaments held weekly at PC bangs allow players to hone their skills for competitive gameplay. Gamers learn from each other, gaining experience to boost all characters. In particular, esports is now a rapidly growing industry, as more and more young gamers choose professional gaming to build a career path in Korea. The top-ranked esports titles that are played in PC bangs include *Sudden Attack* (2005), *League of Legends* (2009), *StarCraft II: Wings of Liberty* (2010), *Counter-Strike: Global Offensive* (2012), *Dota 2* (2013), *Hearthstone* (2014), *Heroes of the Storm* (2015), *Overwatch* (2016), and *PlayerUnknown's Battlegrounds* (2017).

Second, in the economic dimension, PC bangs also benefit the Korean game

industry by functioning as a stable network for game delivery. The success of *Lineage* and *MapleStory*, through PC bangs, helped Korean game developers NCSoft and Nexon try out innovative payment and distribution models for online games (Huhh 2007).

However, the PC bang industry has also had a controversial impact on Korean society. In 2006, some PC bangs were shut down during the “Sea Story” scandal, which involved large-scale illegal internet gambling. In 2011, the Korean government passed a shutdown law, the Youth Protection Revision Act, to solve the problem of internet addiction. Also known as the Cinderella Law, it regulates teens from playing computer games from midnight to 6:00 am. In 2013, the Korean government enacted a smoke-free law in public places that also includes smoking bans at the PC bangs. PC bang owners objected to both laws during the legislation process.

Performance

Digital performance has its roots in many overlaps between different artistic and scholarly fields. Since the 1970s, performance studies has emerged as an interdisciplinary research field that expands from theater studies but concentrates on the analysis of performative actions and behaviors (Schechner 2002). It includes aspects of more established fields, such as anthropology, communication, psychology, gender studies, or theater studies, but distinguishes itself from neighboring disciplines through its focus on the performance itself (instead of, e.g., the written text). From the position of performance studies, *digital performance* has been defined as “all performance works where computer technologies play a *key* role rather than a subsidiary one in content, techniques, aesthetics, or delivery forms” (Dixon 2007, 3). The increasing use of various media in experimental performance pieces that include not only video but also real-time three-dimensional imagery, robots, and hybrid stages has strengthened connections between the development of performance art and interfaces of evolving new media (Chatzichristodoulou, Jefferies, and Zerihan 2009; Dixon 2007), and it has actively contributed to the intermediality of performances (Chapple and Kattenbelt 2006) as well as their documentation and archiving. In return, the media-driven and technological aspects have taken on

a growing role in the theory of performance studies affecting is production (McKenzie 2001), liveness (Auslander 2008), and audiences, among other facets.

Focusing on performance as a process and discussing possibilities of performing machinery bears close connections to interactive media, which also highlights procedural qualities and forms of participation. “Computers as theatre” (Laurel 1991) have been discussed in the field of interface design, and games have been presented as “cyberdramas” (Murray 2004) that provide certain narrative and dramatic opportunities. These cases allow a reinterpretation of players as interactors, game worlds as virtual stages, and play as performance. The resulting influences of dramatic arts can be traced in human-computer interaction design, artificial intelligence, and virtual character and game designs, to name a few of the evolving connections. Interaction designers have been inspired by scholars and performance artists from Aristotle to Brecht, Boal, and Kaprow, and many research groups have either hosted or collaborated with performing artists such as Laurie Anderson, Blast Theory, STELAR, or Char Davies to produce instances of digital performances (Giannachi 2004). Performance turns to digital technology to gain new expressive tools for a piece acknowledged as performance, framed and situated as an artistic event.

Game scholars, on the other hand, use references to theater and performances to look at games as performances to find a suitable critical frame for the emerging digital expressions available in games. The gap between the two narrows as both fields, performance studies and game

studies, continue to evolve, and a definite categorization of the cross-references between the two is difficult; however, basic questions of body/identity/gender, space and time of the performance, role of the audience, and sociocultural context are overlapping research fields in both disciplines. Even more precise questions regarding the role of the automation, artificial intelligence (AI), the debate on liveness, and the identity of a virtual character are part of the research and artistic practice in both fields.

Peripherals

Peripherals are devices that are connected (via a physical connection such as a cable or a wireless connection via an electronic signal) to a video game console or computer to provide extra functionality, and the term does not usually refer to media storage devices such as cartridges, discs, or memory cards. Television screens and computer monitors function as peripherals to video game systems because they are not usually included in the console itself, but audio speakers and headphones could be included as peripherals.

Apart from screens and speakers, the most common peripherals are game controllers. Some of the earliest controllers were built into game consoles directly, whereas later ones were plugged into a console via cables. Today, many controllers are wireless, allowing players more freedom of movement. Examples of game controllers that are peripherals include devices such as paddles (which are dials), joysticks, Joyboards, joypads, trackballs, light guns, guitars, keyboards, drum sets, and motion-based controllers, such as the Wii Remote (sometimes called the "Wiimote") for the Nintendo Wii.

Besides controllers, there have been a number of other peripherals used with video games to enhance gameplay while not always being necessary to it. For example, the Atari VCS 2600 had keypads for entering numerical information, the Magnavox Odyssey² had a speech and sound effects module called "The Voice," and the GCE/Milton Bradley Vectrex had a light pen that could be used directly on the screen. The SEGA Master System (SMS) could be used with the SEGAScope 3D glasses, and other companies, such as Stereographics Corporation and 3DTV Corporation, produce 3-D glasses that can be used with some video games. The 3rd Space Gaming Vest, by TN Games, uses force-feedback technology to physically simulate the impact of bullet hits, grenade blasts, and other events to the player's torso. The vest uses eight pneumatic air pockets that inflate and deflate in various places around the player's chest and back to simulate directional impacts. There are also a growing number of augmented reality (AR) and virtual reality (VR) peripherals that create new gaming experiences for players.

Some peripherals are used for data storage and work with programmable data storage media. The Famicom Disk System, released in 1986 for the Nintendo Famicom/Nintendo Entertainment System (NES), connected the first console to a proprietary floppy disk drive and used "disk cards" for storage. The NEC PC-Engine/TurboGrafx-16 was the first console to have a CD-ROM peripheral, the TurboGrafx-CD. Other devices, such as the SEGA CD/Mega-CD, also allowed a game system to use a CD-ROM drive. The Nintendo e-Reader scanner, made for the Game Boy Advance and released

in 2001, had an LED scanner that could read encoded data printed on paper cards, which were used by certain games to unlock items or play minigames.

One video game peripheral is not even sold commercially to consumers. The PediSedate, invented by medical doctor Geoffrey Hart, is a headset that attaches to the Nintendo Game Boy and is used to reduce the trauma children feel during medical or dental procedures. As the child plays, the system monitors respiratory functions and delivers nitrous oxide as needed, keeping the child distracted and sedated until the procedure is finished. As this peripheral demonstrates, as video games find new uses, new peripherals will continue to appear that adapt games even more to other tasks and purposes.

Persistent Games

Online gaming experiences taking place in a persistent-state virtual world (PSW) may be referred to as *persistent games*. In their computer-based simulated environments that almost never stop, these games' histories, challenges, and inhabitants are persistently present, twenty-four hours a day, seven days a week. Players

interact directly or through avatars, with rules based on the real world, fantasy worlds, or hybrid variations. These games continually run on servers and guarantee data persistence even if (hypothetically) no one is playing. Some of them keep evolving when the player is disconnected because other users continue playing. Types of persistent games include multiuser domain or multiuser dungeon games (MUDs), massively multiplayer (MMP) games, massively multiplayer online games (MMOGs), and massively multiplayer online role-playing games (MMORPGs). Persistent browser-based games (PBBG) are also accessed and played over the internet directly through a web browser. Game and world persistence may also be partial or simulated: some virtual worlds reset periodically, and multiplayer games may distribute events between different game sessions and mobile devices. Persistent game elements can be noticed in video games from as early as the 1980s, such as *Trade Wars* (1984), designed by Chris Sherrick, or *Orb Wars* (1989).

Persistent games have qualities that single-player and session-based multiplayer games usually do not have: virtual societies partially defined by hundreds or thousands of users simultaneously joining in the same game spaces. This web of social relationships is a major factor in the success or failure of a persistent game, which is composed of many systems. Social systems imply communication, groupings, and often possibilities to participate in organized events and social rituals enacted by players. Several of these groups, like the worlds they flourish in, are persistent from one playing session to another. Developers give various appellations to these officially

structured, and usually large, player associations: organizations, allegiances, guilds, and so on. Political systems that manage voting mechanics may also be present in some persistent games, such as *Dark Ages* (Nexon/KRU Interactive, 1999), as well as multifaceted economic systems, like that of *EVE Online* (CCP Games, 2000). Robust markets allowing in-game currency, goods, and character exchanges, such as in *World of Warcraft* (Blizzard Entertainment, 2004), have also seen the rise of virtual goods sold for real money.

Although the persistent games business is risky, especially for games presenting rich fictional worlds, it can be highly profitable if successfully handled. In this market, scale is a major issue in profitability, mainly because of the substantial fixed operating cost necessary to develop, launch, and run these operations. This is explained by persistent games' particular requirements, such as having (or connecting to) registration, authentication, and billing systems; a client/server networking system; servers with databases independent from the client software to run the game on; and security coding to prevent hacking and cheating. However, the value of the audience is more considerable than its size, as good role players both encourage other players to act reciprocally and keep others in the "magic circle" of the game longer.

Pervasive Games

Pervasive games combine actual and virtual platforms in their gameplay. In a narrow sense, their features are twofold. First, pervasive games are generally understood to be transmedial; they use one or more technological devices or online platforms combined with traditional environments. Second, they integrate actual spaces in the game experience, either by using players' locations for the game's progress or by contextualizing real-life settings as the game space (Benford, Magerkurth, and Ljungstrand 2005). In a broader sense, the concept can refer to games and resulting player behavior that expand the "magic circle" and transfer the game space to an actual context, be it temporal, spatial, or social (Montola, Stenros, and Waern 2009).

Historically, one of the oldest forms of pervasive gaming is scavenger hunting (Montola, Stenros, and Waern 2009,

32–34). An early example of this is letter-boxing, which finds its origins in England in the mid-nineteenth century. In this game, players hide weatherproof boxes and distribute clues of their location across various media, for instance, by making use of postal services. Some more recent forms of pervasive gaming rely on similar principles, such as geocaching. Here, players make use of GPS devices to locate coordinates and retrieve “caches,” containers with certain objects in them. Recent pervasive games are rather hybrid forms of gaming that find their origins in playground games (such as tag), role-playing games, urban games, and mystery games.

The main genres of pervasive games are location-based games, augmented games, and alternate reality games. Location-based games actively use the player’s location to progress the game by using displays, wireless communications, and sensing technologies (Benford, Magerkurth, and Ljungstrand 2005, 56); geocaching is an example of this genre. Similarly, Blast Theory’s multiplayer game *Can You See Me Now?* (2002) is a game of catch that requires actual runners to tag online players. Augmented reality (AR) games are traditional games effectively expanded through various technologies. The first AR game that received mainstream attention was *Pokémon GO* (2016), developed by Niantic, known also for the AR game *Ingress* (2012). A more advanced example of an AR game is *STARS* (Magerkurth et al. 2005), a tabletop variation that uses a smart table, wireless communication, and game software (see Augmented Reality).

Alternate reality games (ARGs) are interactive narratives staged in the real

world that use various media to tell their stories (Montola 2009, 37–40). In this genre, players often cooperate to solve puzzles and challenges. Unlike the previous genres, ARGs are often used as a promotion tool by the media industries. The first ARG game was *Publius Enigma* (1994), which was published before the release of Pink Floyd’s *The Division Bell* (1994). It was followed by the more popular *Beast* (2001), the ARG related to Steven Spielberg’s movie *A.I.: Artificial Intelligence* (2001). Since then, many ARGs have been created by player communities as well, such as *Unfiction* (2002). ARGs are still often used to promote new movies or television series or to add content to existing ones (such as *Lost* [2004–10] and *The Dark Knight* [2008]). They form a prime example of what Henry Jenkins (2006) describes as transmedia storytelling: the spread of narrative content across various media platforms.

As a type of game, pervasive games are still growing, but they are also growing more difficult to define. Persistent games, such as massively multiplayer online role-playing games (MMORPGs), often have an impact on daily life in social terms (as in the establishing of friendships) and economical terms (e.g., the selling of characters). However, they do not meaningfully integrate actual platforms from the real world in their gameplay. Still, some features, such as advertising, blur the boundaries between the virtual and actual. For example, in 2005, *EverQuest* (1999) included an option to order pizzas from Pizza Hut. Likewise, games that recontextualize real life are not always pervasive. Urban games such as parkour, which views the cityscape as a set of obstacles one can use

for free running, transfer the actual environment to a game setting but do not use any additional media. Similarly, it can be argued whether mimetic interfaces (such as Nintendo Wii applications and smart toys) blend the actual and virtual or only enhance existing games.

For players, pervasive gaming is attractive because it enables exciting new forms of play that use unexpected technologies and situations. In popular culture, the film *The Game* (1997) depicts the uncertainty and thrill these games can have for players. Because pervasive games entwine actual life with the play of make-believe, immersion in these games is especially strong (McGonigal 2003). These games also provide many opportunities for creative, emergent play. They often force players to join hands online and off-line, thus motivating co-creativity. Academically, pervasive games have not been very widely discussed. In player communities, however, these games and elements of them continue to develop.

Phenomenology

Phenomenology is a philosophical method used to describe phenomena the way they appear. As opposed to phenomenism (e.g., a "stream of consciousness" description in a novel in which *contingent* presence is given, i.e., what a viewer perceives at a given moment), phenomenology aims at the very logic of phenomena, that is, the essential structure or *necessary* aspects of presence. Thus, among all media, video games are excellent objects for phenomenological analysis.

The term *phenomenology* for the description of phenomena as such was first used in the eighteenth century by Johann H. Lambert (1728–77) and then

became widely known through the book *The Phenomenology of Spirit* (1807) by Georg W. F. Hegel (1770–1831). However, it took until the early twentieth century before the method was accepted as a philosophical approach, when Edmund Husserl (1859–1938), as well as his disciples, successors, and opponents—such as Martin Heidegger (1889–1976)—investigated the phenomenological structure of appearances. The phenomenological movement still persists and has followers all over the world, including the French philosopher Maurice Merleau-Ponty (1908–61), who was heavily criticized by structuralists such as Michel Foucault (1926–84) for an assumed/alleged subject-centric view.

It is due to this critique that the notion prevails to this day that phenomenology always has to deal with how something appears to a particular subject. This notion was also supported by the fact that the basis for Husserl's investigations in most cases was his own experience. One's own experience is indeed a starting point for phenomenology, but not its aim (because this would lead to phenomenalism). Rather, the aim is to abolish anything that is not an appearance because there is the idea of the subject itself (which does not appear as a phenomenon). This so-called phenomenological reduction thereby leads to a crossing out of the subject from philosophy, as it has been introduced by René Descartes (1596–1650) in his *Meditations on First Philosophy* (1641). If the subject can be perceived phenomenologically at all, it is the sum of all perceptions, as David Hume (1711–75) had already claimed in his *Treatise Concerning Human Understanding* (1739–40).

Thus, in some cases, the phenomenology of video games is understood as the

experience of a (bodily existing) subject that has to be taken into consideration when analyzing these artifacts (Mellon and Webb 2006; Nielsen 2010). Such an approach leads directly into a discussion of the question of immersion (Poulin 2008), which is a contingent moment of getting lost in the game world and is phenomenological in approach, not phenomenological. In contradiction to this, a radical crossing out of the subject under phenomenological premise has been claimed by Ian Bogost (2008), who argues that the phenomenology of video games has to be an “alien phenomenology” that describes the experience of the game itself—how it appears to the computer.

As video game studies show, the phenomenological method can be applied without explicit reference to the phenomenological tradition. For example, phenomenological approaches can be found in game classifications, in which games are grouped according to genre definitions or technical qualifications. This is especially the case when video games are addressed as imagery and when their pictorial structure is described. Furthermore, this means that whereas genre classifications describe the content of a game (such as “adventure”) and technical classifications refer to the material basis (such as “arcade”), phenomenological descriptions focus on the medial form of the game's image or the form of possible interactions within it; that is, in a phenomenological perspective, these forms are the main perceptual characteristics of the mediation process.

Some examples include Mark J. P. Wolf's (1997) formal description of the relation between on-screen and off-screen spaces in games and Espen Aarseth et al.'s (2003) typology of games. Both

approaches do not assign themselves to the phenomenological tradition explicitly, but they do describe essential structures of games as they appear, without supposing that the apparent structure is contingent (i.e., subject to individual perception). Whereas Wolf's description follows a historical succession of forms, Aarseth et al.'s phenomenology is transcendental in the strict sense, which means that they do not only give (historical) examples for typical forms but identify the possible realm of the appearance of games. In the case of the spatial appearance of games as phenomena, this means that they can vary within the range of a topological or geometrical gaming principle, as can be found in chess on one hand and a first-person shooting game on the other. For such a transcendental phenomenology, there do not have to be given examples that match the extremes—such as chess being purely “topological” and shooting games being purely “geometrical”—but it is only claimed that all possible games have to be in between these two poles. (e.g., real-time strategy [RTS] games can be topological in respect to navigation but geometrical in respect to combat.) Therefore, with Clara Fernández-Vara et al. (2005), it can be argued that the phenomenological description of video games also has to take into consideration the possible discrepancy between navigational space and visible space.

Transcendental phenomenologies have already been used in art history (and also without being named a phenomenology) to analyze paintings. An example is the Swiss art critic Heinrich Wölfflin (1864–1945), who in his *Principles of Art History* (1915) defined the (transcendental) principles of pictures (being the “condition of

possibilities”), stating that the space of an image can either be “flat”—as in many paintings of the Renaissance—or “deep,” as in many paintings of the Baroque. Flatness, according to Wölfflin, does not mean that there is no perspective with the illusion of visual depth (as was the case in medieval paintings) but rather that elements in the picture are all arranged in the same layer of the picture or that the walls have no textures and there is hardly any variation in illumination, as is the case in Leonardo da Vinci's *Last Supper*. In contrast to that is Velazquez's *The Fable of Arachne*, in which the walls have rich texture, the figures are arranged in different layers, and the z-axis depth is accentuated through shadow and light. This phenomenological approach can easily be applied to game genres; for example, if early first-person shooting games are compared with later ones, the style of space in *Wolfenstein 3D* (1992) is flat compared with that of *DOOM 3* (2004), which is deep. In early shooting games, the floor and ceiling had no textures, and non-player characters (NPCs) acting as opponents were limited to moving within a discrete set of planes set at different distances along the z-axis. The opposite occurs in “baroque” shooters a decade later: all rooms have texture-mapped surfaces, opponents can move freely along the z-axis, and the movement through the game space overall has a higher degree of freedom.

Because the subject (as the agent of experience) is reduced within a phenomenological description, the first person can nevertheless be described as a transcendental phenomenological subject. This is one of the reasons why first-person shooters (FPSs) are, because of

their structure, the best candidates for phenomenological description and also why they are, in turn, crucial for phenomenology itself: FPSs inherit a phenomenological structure known as an *ipseity*. *Ipseity*, or “selfness,” is a term that was explored by the French phenomenologist Michel Henry (1922–2002) in his book *Incarnation: A Philosophy of the Flesh* (2000). The term *flesh*, as a philosophical concept, was introduced by Merleau-Ponty to point out that the subject cannot be conceived as pure thought (as in Descartes’s notion of the thinking essence, or *res cogitans*), but it does have perceptions, sensations, and feelings. In the early works of Merleau-Ponty, such as *Phenomenology of Perception* (1945), those appearances were ascribed to the body, or the corps one possesses (*corps propre*), which nevertheless is still an entity and finally a substitution for the Cartesian ego (and thus was justly criticized). In his later writings, especially in the posthumously published *The Visible and the Invisible* (1964), Merleau-Ponty introduced the concept of the flesh to point out that it is not about the body as a unity but about the body in its sensitivity (flesh thus evokes a body that has even been deprived of its skin) and entanglement with the world, in case of games: the acting within it by means of telepresence (Klevje 2012).

Even though the ego in an FPS is not presented as a full body, its sensitivity is depicted by simulating sensations (like dizziness of the screen or a reddish tinting of vision, both indicating a subjective state) as well as the ability of the image itself to relate. This approach, which considers the ego as an appearance with a structure that is of selfness can also be found in analytic philosophy or

philosophy of language, as in the works of G. E. M. Anscombe (1919–2001), Hector-Neri Castañeda (1924–91), and Roderick M. Chisholm (1916–99), who come to similar conclusions, stating that the *I* is not an entity whose existence can be proven but that there is the (perceivable) perspective of the first person, which cannot be deduced from another perspective (the second person or third person). FPS thus explicate the phenomenological (as well as grammatical) structure of the first person as ipseity (or a “Me”) without claiming the existence of the ego (or an “I”), which in turn leads to the constitution of a “ludic self” (Vella 2015).

FPS basically do this through the perspectival structure in which not only the objects of the image are depicted—as is the case in movies, which also offer a transcendental subjectivity (Crick 2011; Sobchack 1992)—but from which the main game principle is derived, which is the centralization of the pictorial objects at the vanishing point. In addition, the subject’s sensitivity is exemplified through modifications of the pictorial style to indicate a subjective state, such as through coloration or blurring (when the subject of the first-person perspective gets shot). Philosophically speaking, video games can offer insight into theoretical problems regarding phenomenology because of their ability to instantiate an interactive first-person perspective point of view.

Philips CD-i

The Philips CD-i is a multimedia entertainment system released by the Dutch electronics company Philips in North America in late 1991 and Europe in early 1992, which was discontinued in 1996 with support for the system dropped entirely in 1998. CD-i is an acronym for compact disc interactive. It was designed to offer more functionality than a standard CD player while being less expensive than a personal computer; as such, video games were not the focal point of the system’s marketing. As a result, the system was well equipped as a media and

entertainment hub but was underpowered as a gaming console compared to competitors. Playback of CD-i movies required the use of a digital video cartridge (DVC) that needed to be purchased and inserted into the system separately. Later models eventually integrated the DVC into the system itself.

The Philips CD-i had a number of different models with different specifications and price points to address this. Cheaper models were intended for consumer use, and higher-priced models with more features were intended for professional use; these were separated into the 200 series, 300 series, 400 series, and 600 series. The 200 series (205, 210, and 220) were the standard home-consumer editions of the system. The 300 series (310, 350, 360, and 370) were portable versions of the system, which featured an integrated screen and rechargeable battery. The 400 series (450, 470, and 490) were smaller, cheaper models intended for educational purposes, such as classroom use. The 500 series models were the same as the 400 series but with an integrated DVC. Finally, the 600 series (600, 601, 602, 604, 605, 615, and 670) were the larger, more expensive models aimed at professional settings, with support for computer-based additions such as keyboards and floppy disk drives.

The Philips CD-i originated in a deal between Philips and Nintendo to develop a disc-based add-on for the Super Nintendo Entertainment System (SNES). The Philips CD-i also famously featured game franchises licensed, but not produced, by Nintendo. Licenses were granted to Philips in exchange for its help in developing a CD-based console of its own after the Nintendo-PlayStation deal

fell through. While the *Zelda* games on the CD-i received mixed reviews at the time of their release, they have a poor reputation with contemporary fans. *Zelda* series producer Eji Aonuma considers the *Zelda* CD-i games to be noncanon.

There were hundreds of officially released titles for the Philips CD-i across a range of genres and styles. A number of interactive encyclopedias and other learning applications were available for the system in addition to games.

The CD-i was able to play CD video files, and a number of full-motion video (FMV) games took advantage of this, such as *Mad Dog McCree* (1990), *The 7th Guest* (1993), and ports of the laserdisc arcade games *Dragon's Lair* (1983) and *Space Ace* (1983).

In the late 2000s, interest in the Philips CD-i was revived due to cutscenes from CD-i games being used heavily in “YouTube Poop” (Burgess and Green 2018) videos on the video-sharing website YouTube. YTP videos are edits of existing media remixed to be surreal and stranger than the original source material. Animated cutscenes from *Zelda: The Wand of Gamelon* (1993), *Link: The Faces of Evil* (1993) and *Hotel Mario* (1994) were among the favorite CD-i sources for YTP creators. While the intention of the videos was to mock the absurdity of the cutscenes, they also led to renewed interest in the system and games.

The CD-i system was ultimately a commercial and critical failure, reportedly losing Philips \$1 billion across its life cycle before being discontinued in 1996.

Piracy in China

As the largest producer and consumer of pirated video games in the world, China is facing a serious problem in game piracy. Since the introduction of video gaming to China in the 1980s, China has been a land of game piracy for almost three decades; from the Nintendo Famicom to the Nintendo Wii and the Sony PlayStation 4 and from Game & Watch to Nintendo Switch, the condition remains unchanged. Piracy has dominated the home console game market, home computer game market, and the handheld game market. Foreign game

manufacturers have great difficulties launching licensed games in China because of piracy and state censorship.

Game piracy in China exists in various forms, and it penetrates nearly all game platforms and genres, except online games and arcade games. There are four major forms of game piracy in China: software piracy, hardware piracy, digital piracy, and game plagiarism.

Pirated game software made and marketed in China, either in CD-ROM or cartridge format, is always in strong demand because of its low price. The majority of players in China have never purchased licensed games; they use their home consoles or handheld consoles to play pirated software. Sometimes a chip has to be installed in a console to play pirated software. When a customer buys a game console, the shopkeeper will usually insert the chip for free. In recent years, digital piracy has become very common. Players can download a large number of games from certain websites or links for a small fee or for free.

Pirated game hardware and emulators enable players to play games without purchasing licensed game consoles. China used to make pirated game consoles; for instance, in the heyday of the Nintendo Famicom, many unlicensed Famicom-compatible machines were manufactured in China, and some even publicly advertised on television. Today, China is not making unlicensed new-generation game consoles, such as Xbox One, PlayStation 4, and PlayStation Vita, for technological reasons. Another reason is that there are many game emulator programs for people to download for free on the internet. People install the programs so that they can use their computer or handheld console to play

games originally developed for other platforms.

Digital piracy, in place of software piracy, has become the most popular form of game piracy in China. There are many websites in China where people can download games for free. Many have impressive collections of games, and one can find hundreds of titles, old or new, imported or locally made. There are also unlicensed servers where people can play online games.

The plagiarism of game consoles and software is nothing new in China. In particular, the console design is most vulnerable to plagiarism. For instance, the Vii and the PXP800 look exactly like the Wii and the PSP, although they cannot play games designed for the Wii and the PSP. In addition, many Chinese games borrow the character design, story, or system from foreign games. For example, the first *Saint Seiya* online game was actually developed by a Chinese manufacturer without acquiring the copyright from Japan.

The prevalence of game piracy in China was at first caused by the gap between the price of licensed software and the purchasing ability of the people. A set of licensed game software may cost more than RMB 100 (USD 14.60), but a pirated edition costs only a few renminbi. However, following the rise of the standard of living among people in China, the price of licensed game software is no longer unreachable. Yet, the problem of game piracy remains as serious as before. It is because licensed software can hardly survive in the piracy-plagued market, and as a result, many games are not available as legal, licensed software. Consumers are also so used to having a “free lunch” that they are not willing to buy

licensed software. Also, Chinese authorities, regardless of the establishment of antipiracy regulations and agencies, have not been determined enough to crack down on game piracy.

The piracy problem has forced foreign game makers to refrain from entering the Chinese market, undermining the reputation of China in international trade and giving rise to online gaming, which is relatively piracy-free.

Platforms

Broadly speaking, a *platform* is anything built that makes it easier to build other things. “A platform in its purest form,” writes Bogost and Montfort, “is an abstraction, simply a standard or specification” (2007, 2). In the digital realm, “a platform is a computing system of any sort upon which further computing development can be done” (Bogost and Monfort 2009, 2). Platforms

can be implemented as hardware or software, but they often involve both building on each other in layers. Platform studies, an emerging discipline in computation, examines the architecture that enables the “creative works that have been produced on those platforms” (Bogost and Monfort 2007, 176).

Unlike Atari’s *Home PONG* (1975), which was specifically designed to play a single game, the Atari VCS 2600 was constructed to enable developers to write software on interchangeable cartridges that could be executed by the hardware. Understanding this hardware—the 6507 processor, the Television Interface Adapter (TIA), ROM cartridges, and 8-pin controllers—reveals the constraints game programmers worked within when designing games. Because the VCS had no frame buffer for storing video display information, developers had to write carefully timed code that would execute synchronously with the television’s electron beam. Familiarity with the hardware limitations of the VCS graphical display is central to understanding how sprites are drawn and updated, the rectangular shape of the “pixels” on the screen, and the number of processes that could be executed as a CRT television’s electron beam raced across the screen (Bogost and Monfort 2009, 28).

The hardware capabilities of the Nintendo Wii’s motion controller are another kind of platform. The Wii controller uses gyroscopes, accelerometers, and infrared receivers to accept user input. The gyroscopes and accelerometers measure rotational movement and acceleration along the controller’s major axes while the infrared sensor maps the position relative to the television as a cursor

on-screen. The Wii could not interpret complex gestures, so games designed for the hardware could not implement subtle motion. Instead, games were designed to account for the limitations of the hardware. Swinging a racket, golf club, or baseball bat in *Wii Sports* (2006) does not need to map one-to-one with the physical motion of the player because the game does not require that level of fidelity.

Software is equally important to the study of platforms. Software platforms include programming languages, such as BASIC and C++; operating systems, such as Microsoft Windows and Mac OS X; multimedia platforms, such as Adobe Flash; and game graphics and physics engines, such as Valve’s Source and Epic Game’s Unreal Engine. Software platform studies differ from software studies or code studies in that the latter examines how the software was written rather than how others can use it (Bogost and Monfort 2009, 147).

Platform studies is positioned by Montfort and Bogost as the lowest level of five tiers of digital media studies. Each level dives deeper into the object of study as the critical lens moves down through the reception and operation by the user, the interface between the user and object, the form and function of the processes and rules that govern the computational artifact, the code written to instantiate those processes, and the platforms that enable that code to run (Bogost and Monfort 2009, 146). All of these are situated in the culture and context that informs decisions made at every level.

Play

Play scholar Brian Sutton-Smith claims that the task of defining play is “difficult, if not impossible,” given how vast the concept is (1997, 217). He extends this warning by stating, “We all know what playing feels like,” but “when it comes to making theoretical statements about what play is, we fall into silliness.”

The concept of *play* goes hand in hand with *game*, and it is hard to imagine defining one without the other. Yet, major efforts—notably Juul’s (2005)—have focused the attention more on defining *game* rather than *play*. This seems reasonable, as games feel more concrete and specific than the multiple activities involved in play. Still, the challenge of better understanding the latter remains.

Defining *play* can be difficult for several reasons. One is context: the same activity could be perceived as *play* or not

depending on the player’s intentions. For example, I could enjoy solving cypher puzzles. However, if I were a spy, that same activity could be so serious that my life could depend on it. To make things even more complicated, a professional spy can spend his or her time solving puzzles either for fun or as training—or perhaps both at the same time.

And then we have the language problem. Whereas English makes the distinction between *play* and *game*, most Roman languages do not. However, the English language is not extremely precise either: both terms can be used as a noun or a verb. To make things even more difficult, we also love to use these terms metaphorically in everyday talk.

Salen and Zimmerman describe this duality by pointing out that “games are a subset of play,” and “play is an element of games” (2003, 303). In the first case, play is seen as a set of activities, whereas, in the second, it is seen as an object, a characteristic of games.

Several non-English-writing scholars have felt the need to differentiate between two different categories for describing play, even though we should be careful not to assume that they were describing the difference between *play* and *game*. For example, French philosopher André Lalande differentiated between two kinds of *jeu*, describing one of them as a subset of the other, organized through victories and defeats, gains and losses. French scholar Roger Caillois (1961) also introduced two terms, *paidia* and *ludus*, as two extremes of a continuum where he located *jeux* (French for “games” and “play activities”).

So when reviewing a definition of *play* by a non-English-writing scholar, we have to pay special attention to how the

work has been translated. One of the most famous definitions is that of Johan Huizinga; in his *Homo Ludens* (1938), he offers two definitions of *play*. Here is the broader one:

Play [is] a free activity standing quite consciously outside “ordinary” life as being “not serious,” but at the same time absorbing the player intensely and utterly. It is an activity connected with no material interest, and no profit can be gained by it. It proceeds within its own proper boundaries of time and space according to fixed rules and in an orderly manner. It promotes the formation of social groupings which tend to surround themselves with secrecy and to stress their difference from the common world by disguise or other means. (Huizinga 1938, 13)

As Salen and Zimmerman point out (2003, 75), Huizinga’s definition does not differentiate between *play* and *game* and has been heavily criticized in the recent decades for being vague and too broad (Frasca 1997; Juul 2005). The other classic definition is that of Roger Caillois, who describes *jeu* (was he referring to *play*, *game*, or both?) based on six main characteristics: free, separate, uncertain, unproductive, governed by rules, and involving make-believe.

A common trend in many studies on *play* and *games* is the idea that play activities do not involve rules or at least involve less strict rules than games. The problem here may be how we understand the concept of *rule*. Rules are generally understood as social rules that give value to a certain action: “If you steal, you will go to jail,” or “If you score more goals than your opponent, you will win.” However, not all rules are prescriptive. Some simply describe the inner workings of

something or what is possible within a system. For example, imagine a maraca: a sealed container with small objects inside. The governing law of the maracas is that they emit sounds depending on how they are moved. A toddler can play the maracas according to a basic set of rules: if the maraca is still, there is no sound. If I shake the maraca slowly, there is a soft sound. If I shake it hard, the sound is louder. My maraca playing will be constrained by these rules. These are not, however, prescriptive social rules. If I am playing my maracas in a music band, then there is a clear social rule: I must follow the rhythm or I will be perceived as a lousy musician. Rather than saying that games have rules and play does not, it may be better to understand that there are different kinds of rules. For example, Piaget made the difference between *rules* that are understood as social agreements and *regularities* that influence play in presocialized children.

Elliot Avedon and Brian Sutton-Smith first defined *play* as “an exercise of voluntary control systems” (1971). This was later expanded by Sutton-Smith in his *Ambiguity of Play*, where he writes, “Psychologically, I define play as a virtual simulation characterized by staged contingencies of variation, with opportunities for control engendered by either mastery or further chaos” (1997, 231)

Salen and Zimmerman defined *play* as “free movement within a more rigid structure” (2003, 304). This is an elegant definition that can be particularly useful for designers to visualize the ambiguity between freedom and constraints that play imposes on players.

In my own definition of *play*, I have attempted to look further into the

player's mindset while focusing on its subjective nature: "Play is for somebody an engaging activity in which the player believes she has active participation and interprets it as constraining her immediate future to a set of probable scenarios, all of which she is willing to tolerate" (Frasca 2007). The key words here are *every* and *tolerate*: players will not enjoy all consequences of their play actions, but at least they are willing to cope with them.

Near the end of the *Ambiguity of Play*, Sutton-Smith provides a metadefinition: a list of requirements that he thinks a good definition of *play* must include. These are summarized as follows:

- Play's definition must be broad rather than narrow. . . .
- . . . It should apply to animals as well as humans, and children as well as adults.
- [Play] should not be defined only in terms of the restricted modern Western values that say that it is nonproductive, rational, voluntary, and fun. . . .
- . . . Play is not just an attitude or an experience; it is always characterized by its own distinct performances and stylizations.
- Play can be very narrow or very broad, both in spatial and temporal terms.
- . . . Play is like language: a system of communication and expression. . . . (Sutton-Smith 1997, 218–219)

The fact that one of the most ambitious modern treatises on play finishes not with a clear-cut definition but rather with a blueprint for one is quite telling on how difficult the task of understanding play is.

Play Meter Magazine

Play Meter magazine was a trade publication covering the coin-operated entertainment industry. Founded in 1974 by Ralph C. Lally II, *Play Meter* published monthly until 2018. The magazine offered news coverage at the regional, national, and international levels as well as tournament and league news, coverage of major trade shows, industry trend reports, company profiles, and family entertainment center information. *Play*

Meter's target audience consisted of members of the coin-operated amusement industry, specifically route operators and coin-op machine distributors.

Because of this industrial focus, the publication dedicated much of its space to news of specialized interest to these business sectors. The magazine offered new product descriptions and game reviews that were intended to help operators decide which games to invest in. The magazine also accepted both display and classified advertisements, many of which were focused on specific games or on specific sales or distribution outlets for games. The publication provided other information that may have been of interest to owners and operators who primarily worked with arcades or other dedicated gaming venues and included extensive coverage of non-coin-operated amusements such as miniature golf and go-karts, among others, which are relevant to operators of family entertainment centers. *Play Meter* regularly published tax advice and other content intended to assist in the development and operation of coin-op businesses.

Play Meter included an annual directory issue that listed manufacturers, distributors, and suppliers. The magazine was primarily distributed through mail order, although issues were sometimes circulated at relevant trade shows and were routinely sent out to advertisers or other potentially interested parties. In 2010, subscriptions totaled just under three thousand, with circulation totaling just under five thousand.

In addition to its print presence, *Play Meter* regularly posted industry news in digest form on its website, which currently persists as an online archive.

Playrix

Playrix, or Playrix Entertainment, was founded in 2004 by Dmitri and Igor Bukhman. The company initially provided casual PC downloadable games, and it published its games on portals such as Big Fish Games (a portal specializing in the distribution of such games). Its flagship title, *Gardenscapes* (2012), actually started out as a hidden object game for PCs. Playrix took the mobile turn in 2010; after having launched premium games, the company opted for free-to-play (F2P) games. Playrix specializes in casual titles, such as match-three puzzle games and town simulations.

The company introduces itself as one of the world's top mobile games and PC/Mac games developers, and it employs over eight hundred people across several offices in different countries. Pocket gamer.biz notes that "Playrix has become a best-in-class mobile games studio for maintaining—and, more impressively, actively improving—the profitability of its free-to-play games long after launch" (Suckley 2017). The company has released four successful mobile F2P games: *Gardenscapes* (2012), *Township* (2013), *Fishdom*

(2015), and *Homescapes* (2017). These games have been in the top fifteen of the top fifty grossing games in more than fifty countries worldwide (Takahashi 2016). In late August 2016, Playrix became the first Russian publisher to be ranked globally as a top twenty game publisher by revenue (App Annie 2016). In August 2017, Playrix became the highest-grossing mobile game developer in Europe. As of March 2018, it was the fourth highest on Android and the sixth highest on iOS worldwide, improving its rankings over the previous year (Appodeal and Newzoo 2018, 11). Playrix was ranked eighth on PocketGamer.biz's Top 50 Developer 2018 list.

The company, being private, does not disclose its revenues; however, it has been reported (Harris 2018) that Playrix's match-three puzzle game *Homescapes* generated revenues of \$420 million in its first year from in-app purchases, and that *Gardenscapes* recently hit the \$880 million milestone.

Playrix illustrates the winning strategy of a global export-driven company building on the worldwide growth of mobile devices. As of 2018, the Russian games market was estimated by Newzoo (2018) at \$1.7 billion, and the turnover of the company is likely to be close to that amount if one just adds up the sales of the two games previously mentioned. The company from Vologda chose to self-publish and localize its first hit mobile game, *Township*, into twelve languages, including Chinese, Japanese, and Korean. As stressed by App Annie (2017), "the number of successful self-publishing cases is very small," especially when addressing Asian markets; a successful approach achieved "without changing their game mechanics while

exclusively relying on international ad networks."

Pokémon GO

Pokémon GO (2016) represents one of Nintendo’s most successful forays into the app market. It was published and developed by Niantic, a then little-known studio responsible for the augmented reality (AR) mobile game *Ingress* (2012). Since the game’s release, over one billion people have downloaded it (Webster 2019).

To play, a player must create an account, often linking a Google or Facebook account in the process. The player then makes an avatar with limited customization options before being treated to a bird’s-eye view of his or her location. As the player walks around the map, the avatar matches the player’s location. Pokémon appear when the player draws near. Tapping the Pokémon opens a new screen in which a player can swipe the screen to throw Poké Balls at the desired target. If a Poké Ball hits the

target at the correct time, the likelihood of a catch event increases. Capturing Pokémon is one means to acquire experience points. Through experience points, the character levels up, gaining more items and in-game benefits. There are a variety of items also available for purchase via real or in-game currency. Some items assist in capturing Pokémon, such as berries, while others, such as the incense, draw rare Pokémon to the player.

Another way to acquire items revolves around visiting PokéStops. A nearby player can swipe these stations, earning a small number of items and experience points. Some PokéStops have gyms in which the players can battle Pokémon left by others. These gyms function like king of the hill, with the victor gaining the right to place a Pokémon at that location for subsequent battles. Players are rewarded with in-game currency based on how long their Pokémon holds the gym before being replaced.

A notable departure from the core franchise lies in the treatment of Pokémon as an in-game resource. In the core games, players were encouraged to approach collecting like field biologists collecting samples. The catch phrase “Gotta Catch ’Em All” refers to this challenge, encouraging players to collect one of each kind of Pokémon in the game. In *Pokémon GO*, the dominant strategy is to catch every Pokémon encountered. These Pokémon can be exchanged for in-game resources.

The success of *Pokémon GO* has affected the design methods for Pokémon games for the Nintendo 3DS and Switch consoles as well. In *Pokémon Ultra Sun and Ultra Moon* (2017), the interface was streamlined, moving it

Characters from the augmented reality game *Pokémon GO*. (Mariayunira/Dreamstime.com)

closer to *Pokémon GO*. A concerted effort to combine elements of the app into the console series appears in the design of *Pokémon: Let's Go, Pikachu!* (2018) and *Let's Go, Eevee!* (2018), including using the app's catching mechanics and allowing for trades between *Pokémon Go* and *Pokémon Let's Go* accounts (Webster 2019).

According to the review aggregator Metacritic, the critical response remains fairly mixed. Many reviewers found the gameplay shallow and cited numerous technical difficulties, at times rendering the game unplayable. Despite lukewarm reviews, the game exploded to the top of the app store within the first week of release (July 6, 2016). Usage peaked around July 15, and by September of that year, the game had hemorrhaged 79 percent of its players (Thier 2016). As of May

2018, *Pokémon GO* had 147 million active players, providing a monthly revenue of \$104 million (Phillips 2018). The staggering financial success of the game has renewed interest in the commercial potential of AR games and apps.

Poland

The early days of gaming in Poland were conditioned by the digital isolation of the Communist Eastern Bloc. Western companies were banned from selling new technologies to the East because of the possibility of their military application (Budziszewski 2015). This resulted in a technological delay, as products introduced to the Polish market had to be obsolete from the Western point of view. Private importers were facing harsh exchange rates between the Polish złoty and Western currencies. For Polish citizens to be able to buy a computer or a gaming console in the West, the machine had to be old enough to be sold for a fraction of its original retail price. This continued in the 1990s, even after the removal of the ban, as the purchasing power of Polish society rose slowly. The result of this was a unique situation in which the country repeated the history of computing in an accelerated fashion, with new machines becoming dominant on the market roughly every two years.

The price factor was the main reason for the limited popularity of gaming consoles. Computers were perceived as universal tools suitable for education, and the purchase of dedicated gaming

machines was seen as a luxury. The prices of console games constituted an unsurmountable barrier for Polish players until the 2000s. In the 1980s, software piracy was practically the only way to obtain new games. Piracy was not perceived as problematic because the law did not regulate intellectual property of digital goods until 1994. Cartridges used in most of the popular consoles of the time could not be pirated without manufacturing technologies, and these were unavailable in Poland. For this reason, the first console to reach a mass audience was the Pegasus (a Chinese Famicom clone), which was sold with cartridges containing multiple NES and Famicom games (as well as ROM hacks). Mirroring the digital delay characteristic for the introduction of computers, the 8-bit Pegasus debuted on the Polish market in 1992, when the West moved toward 16-bit consoles. The significance of piracy can be seen in that the next console to gain popularity—one that fully established the console market in the country—was the Sony PlayStation, which was very easy to modify so that it could play pirated CDs. Domestic attempts at creating a Polish console stopped after a few tries in the late 1970s and early 1980s. The most successful of these attempts was the *PONG* clone TVG-10 released in 1979. It came with a preinstalled set of games and was not programmable, typical for early *PONG*-like machines, which also solved the problem of cartridge manufacturing and distribution.

For similar reasons, the only handheld machines that gained popularity contained preinstalled games and were clones of the Nintendo Game & Watch series produced in the USSR. The lack of access to consoles and handhelds resulted in

noticeable differences in gaming culture; popular characters such as Mario and Zelda could not achieve the status they had in the West.

Unlike consoles games, computer games were typically very easy to obtain. Games stored on cassette tapes could be easily replicated using quality double cassette decks. Games stored on floppy disks could be copied using dedicated software (such as *Fast Hack'em* (1985) for the Commodore 64 or *X-Copy* (1988) on the Amiga). Some of the games were even distributed using a state-owned radio broadcasting service and the popular program *Radiokomputer*. Still, the crucial nod in this distribution network can be traced back to “computer sales” (*gięldy komputerowe*). The name of this very Polish phenomenon can be misleading, as there is no good translation of the term to English (in fact, the Polish name is not accurate either). The best way to understand “sales” is to imagine them as hybrids of electronic markets, computer clubs, and demoscene cosparties. The sellers were typically young gamers who sold the games to sustain their hobby. They often swapped new games and played them during the sale. The games were typically sold in bulk, with one tape containing more than a dozen titles.

The fact that in the pre-internet era people had to communicate personally to copy games resulted in an emergence of a strong social network that formed the backbone of a big part of the Polish game development scene. For example, the roots of two of the most successful companies, Metropolis Software and CD Projekt, can be traced back to “computer sales.”

One of the important results of the digital isolation of the Eastern Bloc was a

lack of computer literacy among Poles. Good documentation, manuals, and computer programming books were hard to find. Importing literature from the West was problematic because of the price and the language barrier. The situation started to change slowly thanks to the domestic market of computer magazines, such as *IKS* (1986–89) and especially *Bajtek* (1985–96), which played a formative role for Polish developers. Long game listings written in different dialects of BASIC could be found on many pages of these magazines. In many cases, they were reprints or modifications of similar listings printed in Western magazines, but the magazines sometimes printed original work (Kluska and Rozwadowski 2011).

Apart from listings, the magazines also contained walkthroughs of games (often accompanied by big hand-drawn maps) and a small number of reviews. In 1991, the first magazine dedicated to games was launched. Its name, *Top Secret*, corresponded with its content, as it mostly functioned as a repository of “secrets,” such as walkthroughs, tips and tricks, and simple game hacks. Even though it was never admitted in the magazine, the editors knew that their readers used pirated software, and because of this, a standard Western form of review understood as a buying guide was superfluous. What was needed instead was the game’s documentation. For this reason, the early reviews read more like parts of the missing game manuals; they often started with a short story presenting the narrative of the game and proceeded with a detailed explanation of its controls. In the late 1990s, the Polish gaming press market was at its zenith with twenty-four published gaming magazines

(Kolasa 2001). Hardly any of these titles remain in circulation today, despite crowdfunded attempts at reviving them. Yet, their legacy continues with the newest gaming magazine, *Pixel* (launched in 2015), which was created by many veteran journalists of the era.

The first documented Polish games were adaptations of traditional games written for mainframes: *Noughts and Crosses* (1960) and *Marienbad* (1962), a version of Chinese logic game Nim (Kluska and Rozwadowski 2011). The next significant wave of games appeared in the 1980s, coinciding with the appearance of home computing. The first Polish games came from hobbyists who did not attempt to publish their creations. Apart from the listings already mentioned, a number of simple games for the ZX81 were produced (Kluska and Rozwadowski 2011). The lack of computer literacy and the practically nonexistent legal market resulted in a relatively slow start to an organized development scene. Polish developers could not compete with their Western colleagues on the technical level, and it was also impossible to make the games competitive in terms of their price, as any game released legally had to be more expensive than pirated products.

An ideal solution was to try to sell games directly to the West. This was not easy, as it required the creators to have good connections outside of the Iron Curtain as well as the skills and tools needed for competitive development. The earliest example of this strategy can be found in *Web Master* (1983), an arcade game created for the 8-bit Atari computers. It was commissioned by a Polish emigrant living in the United States, but, sadly, it was never released. A number of

games were created by California Dreams, a company created by another Polish emigrant, Lucjan D. Wencel. The company published a number of fairly successful games released in 1989 for various platforms, such as *Blockout* (a three-dimensional variation of *Tetris* [1984] released for the Amiga, Atari ST, Commodore 64, and PC), *Street Rod* (a racing game released for the Amiga, Commodore 64, and the PC), and *Tunnels of Armageddon* (a pseudo three-dimensional shooting game released for the Amiga, Apple IIGS, and PC). The last of the company's games was *Solidarność* (1991), a strategy game depicting the fight between the famous trade union and the Communist state. The game was finished but never officially released because it was originally planned as a tie-in for a movie about Lech Wałęsa that was never made (Warner Bros. bought the rights but never proceeded with the project). The game leaked and can be played today with DosBox.

The typical strategy employed by Polish developers was to focus on niches neglected by the West. The most obvious one was the lack of games available in the Polish language. This was especially problematic in the case of text adventures, which demanded fairly good command of English. For this reason, the genre became one of the most popular to be developed locally. The first commercially published Polish game, *Puszka Pandory* (*Pandora's Box*), released for the ZX Spectrum in 1986, was quickly followed by a series of other successful text adventures, such as *Hibernatus* (1987), *Conan* (1987), and *Mózgprocesor* (1989), the latter of which was later ported to 8-bit Atari computers. Another important niche for Polish games was

educational software, with games such as *Hexana* (1987) and *Podróż po Polsce* (1987) teaching players mathematics and geography, respectively.

The first wave of ZX Spectrum games passed relatively quickly, as most of the users started to move toward a more advanced platform, the 8-bit Atari computers. The year 1989 saw the release of *Robbo*, a cross between *Boulder Dash* (1984) and *Sokoban* (1982), which remains popular to this day due to the level editor released later. The situation of the 8-bit Atari computer in Poland was unique in that when it became a dominant platform in 1990, there was practically no longer any software produced for it in the West. This created a niche Polish developers needed. Between 1989 and 1994, a number of very successful games were produced for the platform, and many of them, such as *Misja* (1990), *Mieczy Valdgira* (1991), and *Magia Kryształu* (1992), were hybrids of adventure games and platform games, similar to Codemasters' *Dizzy* series of the 1980s and 1990s. Others, such as *Fred* (1991) and *Operation Blood* (1992), belonged to genres that Atari 8-bit computer software lacked: platformers and rail shooters, respectively. Another strategy was to produce unlicensed games based on popular Polish movies or TV shows, such as *AD 2044* (1991), *Hans Kloss* (1992), and *Janosik* (1994). Despite piracy, the demand for new Atari games was so great that game publishing became a sustainable business.

Between 1992 and 1994, the Commodore 64 (C64) dominated the market, but the need for locally produced games was smaller due to the existence of software produced abroad. Still, a number of successful C64 platformers, such as *Lazarus*

(1994), *Slaterman* (1994) and *Eternal* (1995), were released.

The period between 1994 and 1996 belonged to the Commodore Amiga. Similar to the 8-bit Atari computer, Polish development for the Amiga exploded when the number of games released in the West decreased. Many of these games were written in AMOS, a fairly powerful variation of BASIC that democratized game development and enabled amateur programmers to create competitive games without needing advanced technical skills. Many Amiga games tried to tap into themes neglected by Western developers; they were either adventures written in Polish (e.g., *Mentor* [1994], *Misja Harolda* [1995], *Kajko i Kokosz* [1995], and *Alfabet Śmierci* [1996]) or action games set in a recognizable domestic setting (e.g., *Franko* [1994], *Doman* [1995], and *Ubek* [1995]).

Another important influence on Amiga developers was the rise of the PC as a gaming platform. Skilled Polish developers (who often originated from demoscenes) attempted to recreate new PC genres that had limited presence on the Amiga. The effect of this was a number of attempts at creating three-dimensional shooting games (e.g., *Za żelazną bramą* [1995], *Project Battlefield* [1995], *Cytadela* [1995]); real-time strategy (RTS) games (e.g., *Exodus: The Last War* [2000]); *Heroes of Might and Magic: A Strategic Quest* (1995) derivatives (e.g., *Legion* [1996]); and even FMV games (e.g., *Zdzisław: Heroes of the Galaxy 3D* [1997]).

Around 1996, developing games for the Amiga became unprofitable as the market moved toward PC gaming. Early attempts at PC development (e.g., *Electro Body* [1992]) tried to exploit another

niche, the lack of PC platformers, but around 1996, when PC became the dominant platform (which is still the case today), the number of exploitable niches decreased.

The PC was a healthy platform with a steady stream of new games from the West. Many games were localized, so the advantage of using the Polish language was lost. Local developers had only two possibilities: to “chase the West” and create games that were competitive or to sell games cheaply. The latter choice has been exploited by City Interactive, which developed a significant number of low-budget shooters, such as *Wing of Honor* (2003) and *Terrorist Takedown* (2004). The first company that embraced the ethos of “chasing the West” was Metropolis Software, with adventure games such as *Teenagent* (1995) and *Książę i Tchórz* (1996). This was quickly followed by other developers (e.g., Detalion), who made a series of attempts at creating successful *Myst* (1993) clones, such as *Reah: Face the Unknown* (1998) and *Schism* (2001).

The breakthrough moment came with Metropolis Software’s *Painkiller* (2004), a three-dimensional shooter very well received globally. Soon after, a number of developers from Metropolis created a new company, People Can Fly, which entered a partnership with Epic Games and created the PC port of *Gears of War* (2007) and followed it with *Bulletstorm* (2011). After being acquired by Epic Games and renamed Epic Games Poland, the company released *Gears of War: Judgement* (2013) and co-created the worldwide phenomenon *Fortnite* (2017).

Another company with global success, Techland, produced the *Call of Juarez* series (2005–13) of Wild West shooters and *Dead Island* (2011), which was

quickly followed by a spiritual successor, *Dying Light* (2015).

Last but not least, a newly created subsidiary of game publisher CD Projekt developed *The Witcher* series (2007–15), three increasingly well-received three-dimensional action role-playing games (RPGs) based on the Polish fantasy novels by Andrzej Sapkowski.

The rise of the indie (independent) games scene came with new opportunities. Freed from the constraints of the need to chase the West on the technological level and open to self-publishing, developers could create very different games that did not have to fill any particular niche. Arguably, the first game belonging to this category is *Soldat* (2002), a 2-D multiplayer shooter that continues to receive new levels to this day. More contemporary examples include *Zombie Driver* (2009), *This War of Mine* (2014), *The Vanishing of Ethan Carter* (2014), *Superhot* (2016), *Darkwood* (2017), *Observer* (2017), *House Flipper* (2018), and a big number of hidden object puzzle adventure (HOPA) games created by Artifex Mundi.

PONG

The ball-and-paddle game *PONG* (1972) is considered the video arcade game that launched a multibillion-dollar industry and a fevered excitement for high-tech entertainment. Although not the first video arcade game, *PONG*'s design and gameplay contained a formula perfect for the ideals of casual gameplay: curiosity, intrigue, amazement, and simplicity. The *PONG* prototype was built by Allan Alcorn, Atari/Syzygy's first engineer. Nolan Bushnell instructed Alcorn to build a tennis-type game; Alcorn added the on-screen scoring, and after probing the board, found the unique *PONG* sound that he added to the game. Also, a little-known feature of the *PONG* arcade game that Alcorn added is the "hole" in the upper corners of the playfield, which were made so that a player's paddle could not fully reach to the top of each side of the playfield. This was added so that if two players were so good that they never missed a shot, the ball would eventually slip through this "hole," ensuring that the two players could not play a never-ending game, essentially keeping others from playing it, and, more importantly, to get more quarters into the machine, further increasing profits.

PONG was first introduced in a test run at Andy Capp's Tavern in Sunnyvale, California, where patrons were greeted by a small brownish-orange box placed atop a wine barrel, with only the word "PONG" on the control panel to identify this unique device. Of note, the game had an *attract screen* to draw in the patrons; the ball bounced about the screen endlessly while the game awaited a quarter to be inserted. Alcorn explained that the attract mode was purposefully designed

for *PONG* to show the ball moving about the screen, but the paddles did not show so that people would not randomly play with the knobs (according to an e-mail from Alcorn to one of the authors, July 2011). Also, there was no sound during the attract mode for fear that an annoyed bar owner would pull the plug on the unit, defeating the point of its running and making money. Upon inserting a coin, *PONG* reset itself and displayed player paddles on the left and right sides as well as a score display.

The oft told story of the "broken *PONG*" is in fact a truthful one and not just a by-product of the usual video game industry lore and marketing. Atari did in fact receive a phone call from the owner of Andy Capp's Tavern saying that the

People playing *PONG* during Games Week 2014, in Milan, Italy. (Tixtis/Dreamstime.com)

PONG test unit had stopped working. On the side of the orange test *PONG* was a coin mechanism that was used on commercial washing machines of the day. What had occurred, to everyone's surprise, was the type of "problem" desired for every newly tested product: the coin mechanism was jammed because it was completely filled with quarters.

After this initial test, Alcorn and Atari cofounder Ted Dabney went on to hand build ten *PONG* boards to be installed in the full-sized and now-familiar yellow *PONG* cabinets that were also placed at various locations for testing. After the profit results started to come in, Bushnell and Dabney faced a serious problem. They thought no one at Bally, the company they were actually contracted to deliver a video game to, would believe the profit results. They were just too good for such a new and unproven technology, especially compared with what new pin-ball and electromechanical games normally made at the time. When it was time to report to Bally, Bushnell and Dabney lowered the profit results by 25 percent per location, but Bally still responded that the results were not believable—they were just too high.

Bushnell and Dabney were then faced with another dilemma. They saw that *PONG* was making money, a lot more than anticipated. So they had to consider changing their focus from entertainment engineering to becoming a video game manufacturer. If they were going to do this, however, they would need to convince Bally that it did not want *PONG*. Atari's contract with Bally was to deliver a game to them—any game—so Bushnell and Dabney worked on a letter to send to Bally saying that *PONG* was not a viable game design and that Atari

would deliver a different game to them in its place. Bally accepted the change of game design freely, and Bushnell and Dabney proceeded to go it alone and produce *PONG* machines directly.

PONG machines arrived at locations in all shapes and sizes, from the most well-known upright, yellow-faced cabinet to a cocktail table version. There were *PONG*s housed in used wine barrels, and there was even an experiment in putting *PONG*s into a doghouse-shaped cabinet with a familiar cartoon beagle sleeping on top. In total, 38,000 *PONG* machines (including follow-ups such as *PONG Doubles* [1973] and *Quadrupong* [1974]) were produced and sold to arcades, until 1975, when *PONG* went home—to the living room, that is. The invasion of people's television sets would start a new chapter in Atari's history as the arcade game company began its entry into the consumer arena.

Portal Series

Valve's *Portal* (2007) is a single-player first-person shooting game, puzzle game, and platformer. The game's protagonist, Chell (modeled after actress Alésia Glide-well), is a test subject for the Aperture

Science Handheld Portal Device, a gun that can place a portal on some solid surfaces, allowing nonadjacent spaces to be linked together. Chell's guide to the experimental process, a robot named GLaDOS (Genetic Lifeform and Disk Operating System, voiced by Ellen McLain), begins by helping the player navigate the increasingly dangerous environments of the game, becoming less helpful and more menacing as the player completes more puzzles. The player's increasing proficiency with the portal gun and growing suspicion of GLaDOS's intentions reaches a climax when Chell must destroy GLaDOS to escape the testing facility.

Portal began development after Valve was impressed by *Narbacular Drop* (2005), a senior project by students from the DigiPen Institute of Technology. Gabe Newell, the managing director of Valve, hired the entire team to expand the game's central portal mechanic for a new project at the company. The *Seattle Times* called the developers' journey from students to developers a "Cinderella tale," crediting Newell's scouting of new talent as the key to Valve's innovative new releases (Dudley 2011). Kim Swift, the producer of *Narbacular Drop*, became the lead designer for *Portal*. Writers Erik Wolpaw and Chet Faliszek were also hired for the game (Edge Staff 2008).

Although the interface of *Portal* is similar to most first-person shooting games, with the player maneuvering the player character's viewpoint and gun, *Portal's* gameplay centers around spatial problem-solving rather than fast-paced combat. Patrick LeMieux and Stephanie Boluk suggest a new genre label for *Portal* and other games that "feature the

manipulation of space and time as their main gameplay mechanic," calling them "eccentric games" (LeMieux and Boluk 2009). Each stage of the game requires the player to use the ability to create portals to successfully navigate a perilous three-dimensional environment. The Handheld Portal Device can be used to enter unreachable rooms and move objects from place to place, but the conservation of momentum between portals also leads to the player using portals to launch himself or herself around the space. Although the device does not shoot bullets, it can transfer bullets from place to place, and shooting a portal under an enemy may destabilize it, causing it to malfunction. In *Portal 2* (2011), the device is also used to move lasers (Thermal Discouragement Beams), platforms and passageways (the Hard Light Bridge and Excursion Funnel), and gels (propulsion, repulsion, conversion, and cleansing) that change the properties of surfaces.

Earlier stages in each game allow the player to explore less dangerous and challenging rooms, whereas later stages feature deadly liquid, robots shooting at the player, and other obstacles. In *Portal*, early stages take place in a clinical, featureless setting, with tiles and signs serving as guides. Later in the game, the player must sneak around behind the scenes, using the mechanics the player has learned against the facility itself. Nicolas Schiller argues that *Portal* serves as a model for successful pedagogy because of the way the increasing difficulty of its levels, and the decreasing guidance offered by GLaDOS over the course of the game, teaches the player how to use the portal gun and navigate the space of the game while playing (Schiller 2008).

Portal is one of the few first-person shooters with a female protagonist. As Chell's character model was based on Alésia Glidewell, who is of Brazilian American and Japanese descent, the protagonist may be interpreted as a woman of color with multiracial European and Asian or South Asian heritage. Repeated references to Aperture Science's "Bring Your Daughter to Work Day" have led to speculation that Chell may be the daughter of an employee of Aperture Science. As in *Metroid Prime* (2002), in which the player can sometimes see Samus's face reflected in the inside of the helmet of her spacesuit, players learn they are playing as a female character through a mirror effect, looking through the portals they have created at their avatar. The visible and audible cast of *Portal* is all women, including GLaDOS and Standard Sentry Turrets, both voiced by Ellen McLain. In *Portal 2*, some male characters join the cast as foils to Chell and GLaDOS, including Wheatley—an incompetent Intelligence Dampening Sphere introduced to control GLaDOS, voiced by Stephen Merchant—and Cave Johnson (voiced by J. K. Simmons), the folksy yet sadistic founder of Aperture Science.

Lucien Soulban and Harris Orkin term *Portal* a "modern classic" of the first-person shooter genre for its simple narrative "told through text, voiceover, and song" (Soulban and Orkin 2009). The narrative song, "Still Alive," written by Jonathan Coulton, which accompanies the end credits of *Portal*, features GLaDOS taunting the player with her characteristic sarcasm, "I'm not even angry / I'm being so sincere right now / Even though you broke my heart and killed me." The phrase "the cake is a lie," written behind the walls of the facility by

previous test subject Doug Rattman, became an internet meme that was popular from 2007 to 2011 (McCoral 2010).

Noting that the cake, "a girly prize made by women's labor to reward women's labor . . . is the very epitome of deception," Bo Ruberg reads *Portal* as an exercise in "too-close reading" of gender and sexuality in video games. Ruberg complicates the intimate relationships between GLaDOS, Chell, and the Weighted Companion Cube—a cube decorated with pink hearts that the player must incinerate after being told to regard it as a faithful friend in Test Chamber 17. Pin-up-style art of the Companion Cube found within the walls of the Aperture Science Testing Facility, the goading maternal attitude of GLaDOS, the robot's assertion that the facility is her own body, and the penetrative nature of portals are all elements of a connotative queer interpretation of the game (Ruberg 2019, 73–81). The contrast between the surface of Aperture Science and its pasted-together inner workings encourages the player to look for hidden meanings, even those that may seem to be "over-analyzing" (Ruberg 2019, 82).

Michael Burdan and Sean Gouglas also find deeper meaning in the game, reading *Portal* as "an algorithmic exploration of human struggle against algorithmic processes" and praising its "artistic integration of mechanic, narrative, and theme" (Burdan and Gouglas 2012). *Portal*'s criticisms of authoritarian science and Taylorist efficiency, expressed through video games' uniquely rule-based medium, incite the player to rebel against the game's own instructions, notably in Test Chamber 19, in which the player must escape incineration as part

of the conclusion of testing. In this moment, the game requires the player to take life-saving action on behalf of Chell, “without knowing what the goal is” (Burdan and Gouglas 2012).

Ultimately, “design and play of [*Portal*] fully realizes and then transcends many of the core notions and tropes of video games” with its message of freedom, despite its algorithmic form (Burdan and Gouglas 2012). In this way, *Portal* demonstrates the power of video games as an art form.

Portugal

In the 1980s, a revolution arrived from England with Sinclair microcomputers, the ZX-81 and ZX Spectrum. José Oliveira, a college computer science student, received his first ZX-81 for Christmas 1982. After having implemented a program for drawing mathematical functions—such as $y = f(x)$ —Oliveira went further and decided to add a goal and points to the graphics being drawn on the screen, creating the first two Portuguese games, *Laser* (1982) and *Bala* (1982). Oliveira never thought about selling his games, but he managed to distribute them at a coffeehouse, which made him quite popular and suggested that games could become commercial products. In 1983, Marco Carrasco and Rui Tito signed a contract with the British

company Wizard Software for distribution in the United Kingdom of three games written in Assembly language: *Mr. Gulp* (1984), *Defenders* (1984), and *Moon Megatron* (1984).

The year 1985 was a high point for Portuguese pop culture, in music, film, fashion, and video games, which included one of the biggest successes of the Portuguese game industry, *Paradise Café* (1985). Almost anyone who had a ZX Spectrum in Portugal in the 1980s would know the game or at least have heard of it. *Paradise Café* became famous not only for its adult themes, despite the poor quality of its gameplay, but also because one of the elements that contributed most to its success was the fact that it was based on an urban myth, which was a big topic of conversation in coffeehouses throughout the country.

During the 1990s, Portugal commemorated the five hundredth anniversary of the discoveries of Admiral Vasco da Gama and others, which meant a lot of available funding for artwork related to the theme. And in 1998, the Lisbon World Exposition (Expo '98) was held, which would also fund projects related to the oceans and national endeavors. New companies emerged in those years, launching *Aventuras da Peregrinação* (1997), dedicated to the Portuguese explorer Fernão Mendes Pinto and presenting a dramatization of his pilgrimage, and *Vasco da Gama: A Grande Viagem* (*Vasco da Gama: The Great Journey*) (1998), which provided a great multimedia experience.

The company YDreams was founded in June 2000 with the goal of moving forward in the field of new communication technologies. The game development team was small, and development was

carried out on a proprietary YDreams platform; however, in 2003, the company launched the first international location-based commercial game for mobile platforms, *Undercover* (2003), a game with multiplayer abilities. Players could use their location to act, to take shelter in predefined locations, to prevent terrorist attacks, and to use the power of teleportation to travel between places on the map.

Since its inception, the Portuguese video game industry has tried to create a console game, but most of the projects created in the 1990s and 2000s remained incomplete and were never published. Portugal was able to produce a successful console game, for the PlayStation 3 (PS3), with the game *Under Siege* (2011). Completely created and produced by Seed Studios, a company based in Porto, it became one of the ten best-selling indie games in the PS3 network in 2011.

In 2011, with the world economic crisis affecting the entire country, the national audiovisual and video game content production houses collapsed. Most of the companies working in games went into bankruptcy or just gave up the business, with hundreds, maybe thousands, of highly specialized human resources leaving the country for the north of Europe and the United States. The situation only started to normalize in 2013–15; however, most of the workers did not return to the country, leaving most of the companies in a difficult position to restart. On the other hand, universities offered more undergraduate degrees, master's degrees, and specializations in the domain of games, which raised some hopes. Since then, these hopes have been fulfilled with the delivery of dozens of mobile games per year.

The Portuguese video game history is mainly characterized by the production of various highly interesting games and game technologies, but ones without international consequence. This means that throughout the past four decades, we can find highlights in every five-year period; however, these hardly relate to each other, thus failing to grow and empower a Portuguese industry in the domain of game development. This is not unlike the situation faced by the other arts in Portugal, namely the film industry.

Preservation

Preservation is a key component of collecting, organizing, and protecting video games and their cultures. The act of preservation is key to (1) understanding the video game industry and the forms of cultural expression it produces; (2) developing a comparative and historical sense of personal and shared play; (3) cataloging (for later use or the historical record) the range of provocations, prototypes, and production assets that comprise particular creative properties; (4) making

accessible to others primary and secondary research materials; and (5) situating the video game medium alongside other mass media.

In the aggregate, preservation occurs in archives, which are integral to the act of preservation. Archival preservation ideally means storage with comprehensive environmental controls, a physical layout that minimizes human contact with artifacts, and a detailed use plan for the collection.

Preservation strategies and techniques are often idiosyncratic due to the superabundance and variety of video game software, hardware, and associated materials. Preservation is also highly context dependent. For example, some situations call for the preservation of mobile operating systems and devices along with the games they enable, while other situations require particular attention to the environmental conditions within the archive's physical storage space or consideration of the aesthetic and operational toll taken when artifacts are regularly used. Complicating matters further is the fact that the video game industry and its products are so mercurial. Video games have been used as test beds for copy protection schemes, localization strategies, data format and exchange protocols, and distribution channel services; the companies that pioneer such efforts disappear by the dozens every year. All of this introduces a high level of complexity to the act of preservation, and it also means that the art and science of saving video games for posterity is constantly evolving.

Video game preservation efforts tend to focus on physical materials (e.g., paper, plastic, metals, textiles, storage media) as well as the personnel and

supplies that enable an assortment of protective measures (e.g., catalogers, chemists, archival folders). Less commonly discussed, though equally important, is the concept of “preservation through use,” the idea that video game preservation should involve saving the experience of play as well as the material components that enable that experience. Preservation through use holds that because games enable particular kinds of play, it is necessary for that play to be integrated into the preservation enterprise. In other words, games need to be played to be preserved because, without play, a “game” is really just a piece of software. This means thinking about how to maintain games as playable, not just static, artifacts.

Fortunately, the material aspects of game preservation are fairly well understood and have been assiduously explored and tested by archivists in other arenas. Libraries, for instance, know well how to preserve print materials: use acid-free storage folders and boxes; limit exposure to light, moisture, and harmful oils/chemicals; and avoid contact with objects and pests detrimental to paper (e.g., particle board, silverfish). Preserving game instruction/technical manuals, design notebooks, and hand-drawn concept art is thus a relatively straightforward endeavor thanks to the work of print librarians and conservationists over the centuries. Game plastics and other petroleum-based materials similarly require specialized preservation techniques—care for the constituent artifacts themselves (e.g., dissipating their acidic gases via air circulation) and for adjacent objects that may be harmed by such “off-gassing,” for example—and video game archivists are able to look to their

counterparts in film, television, and toy preservation for guidance.

Less well understood are the techniques by which game software can be stored in usable and durable formats. The challenges associated with this type of preservation are substantial and evolving, and they involve the need to address material issues (e.g., the degradation of printed circuit boards and storage media) alongside industrial obstacles (e.g., industrial copy protection mechanisms). Moreover, the video game medium is growing more ephemeral as digital distribution is proving more affordable, secure, and convenient than physical distribution. Video game preservation, therefore, demands a transdisciplinary skill set, often with expertise in areas such as materials science, computer engineering, art history, and more.

In summary, preservation represents the material, architectural, and human factors involved in the safeguarding of video games and their cultures. As such, it stands today as one of game studies’ most diverse and demanding topics.

Procedural Generation

Procedurally generated content is not created by hand but by algorithms that use numerical seeds to mathematically generate objects, which may or may not also involve randomization, depending on whether different output is desired every time a game world is generated. Procedural generation not only keeps a game fresh for players but also for the game's creators, who determine the parameters of algorithms that will automate the production of game space.

The first game with procedurally generated rooms was *Rogue* (1980), which had a series of dungeon rooms that the player wandered through, defeating monsters, collecting treasure, and looking for food. To provide variety, the rooms and the pathways connecting them were procedurally generated, and the randomized placement of monsters, treasures, and food also contributed greatly to the game's replayability. Another game dependent on randomized elements and layout was *Stellar Track* (1981) for the Atari 2600. This *Star Trek*-inspired resource management game had the

player jumping from quadrant to quadrant, using phasers and photon torpedoes to destroy alien vessels. Each of the thirty-six quadrants had sixty-four sectors, creating a playing field grid of 48-by-48 positions. Each position could contain the player's ship, an enemy ship, or a star, which acted as a barrier to travel. Each game was a new challenge due to randomized content.

Randomized content was also the key to making much larger worlds than what could be fit into relatively small amounts of computer memory. The landmark space trading game *Elite* (1984) featured a universe of eight galaxies, each with 256 planets, in a program of only 22 kilobytes. Each planet's position, composition, commodity prices, and name was procedurally generated from numeric seeds fed through an algorithm. But while the starships and other objects were visible from space, one did not get a sense of exploring a more earthlike space, one with vast tracts of explorable land. This would come with the advent of fractal landscapes.

In 1975, Benoit Mandelbrot discovered fractal geometry, which involves shapes that are self-similar at different scales and generates forms similar to natural phenomena (such as fern branches and mountain ranges). Lucasfilm's *Rescue on Fractalus!* (1984) used procedurally generated fractal landscapes; geometric mountains and randomized terrain created more detailed landscapes than the low-resolution graphics were otherwise able to suggest. Fractal technology would again be used in Lucasfilm's *Koronis Rift* (1985), which featured rovers driving over fractal landscapes that were essentially mazes, and *The Eidolon* (1985), which inverted its fractal mountains to

create a mazelike cave interior. Firebird's *The Sentinel* (1986) also used simple fractal-based landscapes and boasted ten thousand levels, stored in less than 70 kilobytes, and Binary Systems' *Starflight* (1986) used fractal landscapes for its eight hundred different planets. However, early fractal landscapes could quickly grow tiresome due to their similarity. Also, terrains with varying slopes can limit accessibility, making areas impassable; it is difficult to ensure accessibility without limiting mountain heights and valley depths, which would homogenize a landscape.

THE VALUE OF HANDCRAFTED PLACES

Fractal landscapes are mathematically unique, but handcrafted locations often have specific attributes that together create a distinct personality that turn a *space* into a *place*. Spaces and activities left to procedural generation tend to be more repetitive in nature, a theme and variations of it, rather than new themes. Games using it can still be fun and replayable with more expansive universes, despite being somewhat repetitive. Mindscape's *Captive* (1990), for example, had 65,535 procedurally generated planets and bases; yet, it received 91percent approval ratings, and *Amiga Power* listed it as the thirty-first best game of all time.

With the arrival of optical disc storage in the late 1980s and early 1990s, graphics improved, and handcrafted worlds became much larger. While procedural terrain generation would continue to be used, increased storage capacity allowed more flexibility, and more detail could be stored and used, allowing more

combinations of handcrafted content and procedural generation. Faster processing times allowed procedural generation to provide more detail in real time and in an increasing number of areas. The *Civilization* game series used procedurally generated maps, allowing players to choose between types of terrain. Smaller scale details changed, but the overall forms remained consistent with the chosen terrain; such variations in detail keep games fresh. But procedural generation is not appropriate for every area of a game, as such material often lacks the deliberate design one finds in material handcrafted by an author.

Combining procedurally generated content with handcrafted material can result in large worlds that have a more deliberate feel in their design, as in *Advanced Dungeons & Dragons: Slayer* (1994) and *Virtual Hydlide* (1995). *Slayer* used repeated wall, door, and window elements in a procedurally generated dungeon that filled in gradually as the dungeon was explored. The designers of *Virtual Hydlide* created over forty maps for the dungeon levels and the overworld, and these maps could be randomly selected and combined. Players would get a ten-letter seed representing a particular world, which could be reentered later. Such reusable seeds also remind us that “procedurally generated” does not always mean “randomly generated”; thus, procedural generation can function as a form of data decompression.

Some games combined various landmasses and buildings to produce procedurally generated towns. *The Elder Scrolls II: Daggerfall* (1996) had a landmass of 62,394 square miles with fifteen thousand towns. Complaints of the monotony of the world led to a much

smaller (only 0.01%) but more handcrafted world for its sequel, *The Elder Scrolls III: Morrowind* (2002). Increased memory capacity helps to solve the problem of repetition in two ways: games can include more handcrafted, interchangeable elements to be used in procedural constructions, or a greater number of algorithms can be used to add parameters to randomization as well as to generate higher levels of detail.

Individual buildings and dungeons can also be generated through the recombination of handcrafted building units; games from the *Diablo* series, for example, are noted for this technique. While repetition in such designs is more evident from a top view, it may be less so from a first-person point of view, especially if the building interiors have randomized elements and décor.

ART GAMES AND THE CHALLENGE OF COMPRESSION

Memory constraints can be an artistic challenge. Programmers attempt to fit detailed worlds within small amounts of memory, relying on procedural generation and faster processing speeds to decompress data, do fractal calculations, and run algorithms. Alessandro Ghignola's *Noctis* (2000) featured a three-dimensional, texture-mapped explorable universe of billions of stars and planets, all generated by a program smaller than one megabyte. Another example is *Kkrieger* (2004), a first-person shooting game with elaborate graphics and lighting, which takes up only 97,280 bytes of disk space, by using box modeling, an iterative process. Models and textures take hundreds of steps to create when the game is run, but the game is able to

produce a world that would normally take hundreds of megabytes to store. Thus, the small amount of memory used must be made up for through processing speed.

Greater storage is also necessary for games that generate large amounts of world data. *Dwarf Fortress* (2006) generates all the terrain of its worlds, along with maps for elevation, temperature, rainfall, drainage, vegetation, and salinity. Mountains are eroded by rivers, and plant and animal populations are added as well as races of sentient beings. Weather modeling even tracks wind and humidity and creates fronts, clouds, storms, and blizzards. After the material world is built, a historical timeline is generated, with thousands of characters being born, living lives, and dying; events are recorded in a year-by-year list for every character's life, where they lived or wandered, who they fought, outcomes of conflicts, descendants, and so forth. Players can choose how much history is generated before the world is ready to enter. Like *Rogue*, graphics are two dimensional and text only, and they appear in sixteen available colors.

Generating three-dimensional terrain, the racing game *Fuel* (2009) provides players with 5,560 square miles of fully explorable terrain, the largest playable environment in a console game. The game is a good example of the graphics that procedural generation can achieve, demonstrating that beyond randomness one needs a set of parameters within which plausible objects and landscapes are generated; yet, even good graphics are not enough to make up for too much repetition of elements. And unlike the simpler worlds of space trading games, three-dimensional worlds

usually must be far more interactive for the player. Games such as *Fuel* allow players to travel all over the landscape exploring, but beyond that interaction is usually rather minimal. However, more fully interactive procedurally generated worlds appeared during the 2000s.

INFINIMINER, MINECRAFT, AND BEYOND

The most popular game with a procedurally generated world, *Minecraft* (2009), was inspired by *Dwarf Fortress* (2006), *Dungeon Keeper* (1997), and especially *Infiniminer* (2009), from which *Minecraft* borrows its ideas, visual design, game-play mechanics, and procedural generation techniques. These games move repetition to a smaller scale; their worlds are composed of variations of blocks combined in endless ways. Although the graphics of these games are simpler, the greater interactivity available outweighs the aesthetic tradeoffs for many gamers. As such, space trading and exploration games continue to evolve, with procedurally generated planets and other locations in games such as *FTL: Faster Than Light* (2012) and *Starbound* (2013) and the eighteen quintillion planets in Hello Games' *No Man's Sky* (2015). *No Man's Sky* also lets players fly down to planets and explore their lands, which are complete with flora, fauna, and geological formations.

What all these game suggest is that we are seeing a shift in which “handcrafted” does not refer to particular instances of objects and locations so much as to sets of parameters governing content generation. How such parameters are set and integrated will be the main ways that human handcrafting is combined with

algorithmically constructed game assets and randomness. As artificially intelligent agents improve and the potential of story structure and world structure are explored and realized, we will likely see the quality of emergent narratives rising as well.

For games to move in the direction of procedurally generated content is quite natural when one considers how much of the complexity of the physical universe is due to procedural processes. As fractal mathematics and the study of cellular automata has demonstrated, simple rules and concepts can generate complex structures, such as a seed growing into a tree or strands of DNA guiding the development of the human body. Video game worlds grown by algorithms are increasing in their complexity, and just as players explore these worlds, their designers are exploring the nature of worlds and their representations. Although they will never reach the elegance and ingenuity of the procedural processes found in the natural world, their striving to imitate them can make us all the more appreciative of the universe around us and its combined simplicity and complexity.

Procedural Rhetoric

Procedural rhetoric is a term coined by Ian Bogost to define a method of rhetoric that involves building and interacting with models rather than with words or images, "the art of persuasion through rule-based representations and interactions rather than the spoken word, writing, images, or moving pictures" (Bogost 2007). Although not limited to video games nor even to computer software, Bogost suggests games as the best medium from which to understand procedural rhetoric. Furthermore, because video games are made from computer models, he argues that procedural rhetoric is the essential meaning-making function of video games, which separates them from all other expressive media. Bogost gives the name "persuasive game" to video games that mount effective procedural rhetoric.

Procedural rhetoric combines two concepts from the history of rhetoric and of computational media. As described by Janet Murray, "procedurality" is one of the key properties of digital media, a computer's "defining ability to execute a series of rules" (Murray 1998). Bogost distances procedurality from Murray's other three properties (spatial, participatory, and encyclopedic) via an Aristotelian virtue argument. The latter three properties exist in other media, but procedurality is

entirely unique to the digital medium. *Rhetoric* refers to the art of persuasion, a practice with a storied history in Western philosophy and creativity. Originally studied for oral communication only, the field of rhetoric was later expanded to include all media and manners of expression, not just those intended to change the opinions of others. The concept of procedural rhetoric stands as an argument against the colonizing efforts of structuralists and semioticians to apply the standards of written rhetoric to video games unthinkingly. Just as visual art requires a unique understanding of visual rhetoric, video games and other interactive software require their own form of rhetoric.

Bogost suggests that procedural rhetoric operates by means of an interaction model based on the Aristotelian enthymeme. An enthymeme omits one premise of an argument and expects the listener to fill it in. Bogost holds that a sophisticated, persuasive game will be able to constrain a player's interactivity in much the same way, finding a game's expressive meaning by following its rules to a designer's premise. Procedural rhetoric can thus be seen as an author-centric design tool standing in opposition to Bogost's reader-centric interpretive tool of the "unit operation," wherein a player interrogates a "simulation gap" between a real-world system and its simulation model within a game to find and synthesize discrete units of meaning among objects, events, and actors (Bogost 2006).

Bogost explores procedural rhetoric in a number of examples from mainstream, educational, political, advertising, and exercise games. In one game from a popular crime simulation franchise, *Grand Theft Auto: San Andreas* (2004), Bogost reveals how the need to eat food to

restore health is coupled with the omnipresence of fast food to create a procedural argument about the rise of obesity in underprivileged socioeconomic classes (Bogost 2007). Molleindustria's *McDonald's Game* (2006), in contrast, shows how the operation of a fast-food conglomerate necessitates unethical business practices. The game's procedures for calculating rising costs quickly overwhelm players, forcing them to practice deforestation, targeted advertising, and cattle hormone feeding to maintain profitability.

The study of procedural rhetoric is closely affiliated with broader arguments about the importance of developing a "procedural literacy" in educational institutions. As literacy is the ability to read, write, and critique a cultural symbol system, procedural literacy specifically deals with skills for reading, writing, and critiquing computer code. In *Newsgames: Journalism at Play*, Bogost, Ferrari, and Schweizer (2010) argue that the general cognitive strategies provided by procedural literacy can be applied, after specific training, to a variety of fields, such as journalism, politics, and economics. Their position is that game design stands as the best way for practitioners of any field to gain a basic competency in procedural literacy.

Miguel Sicart (2011) has criticized procedurality in general and procedural rhetoric in particular as techniques that insufficiently address the player experience of games and that impose a creator's intention on the player.

Another advance in the practical application of procedural rhetoric comes from an analysis of the relationship between processes and graphical skins in *Kaboom!* (1981), an Activision game for

the Atari VCS 2600, about preventing explosives dropped by a "Mad Bomber" from reaching the bottom of the screen by catching them in baskets. Treanor, Mateas, and Wardrip-Fruin (2010) isolate the agents and collision objects of the game and then show how the game's rhetoric changes after manipulating two types of values for each collision: whether a collision is good from the perspective of an object ("evaluative" manipulation) and whether an agent means to do what it does ("volitional" manipulation).

Once these values have been assigned, it becomes possible to reskin the assets of *Kaboom!* to create a virtually infinite number of games within different rhetorical archetypes. Treanor, Mateas, and Wardrip-Fruin (2010) prove that the semantic freight of a game's ruleset is both constrained and context specific. Bogost refers to this phenomenon as the "tight coupling" of visual and procedural rhetorics. Designers that simply reskin a popularly recognized game, such as *PONG* (1972), to raise a political issue without regard for the template game's procedural affordances tend to produce ineffective procedural arguments (Bogost 2007).

The designers of early simulation games can be seen as the forerunners of procedural rhetoric, inspiring many of Bogost's premises and design methodologies. The "mechanics are the message" school of design—personified by Brenda Brathwaite, Soren Johnson, and others—share Bogost's assertion that a game's meaning comes primarily from the interaction between its rules and its players (Johnson 2010). Similarly, developers of "immersive realism" games, such as Patrick Redding, argue that games should allow players to engage with meaning as a lived, systematic experience rather than feeding

players meaning through traditional storytelling methods (Redding 2008).

Psychodynamics

The psychodynamics of video game playing refers to the application of psychoanalytical theory and related

concepts to the experience of playing a video game. This approach uses concepts of Sigmund Freud, Jacques Lacan, and others, following in their footsteps. These theories offer a framework for analyzing the psychosomatic processes occurring during gameplay. Video game playing can be divided into three dimensions, using Lacan's distinctions between the "real," the "symbolic," and the "imaginary" (Lacan 1997, 7–15, 63). In the real rush of digital play, symbolic messages are exchanged between program and player that produce an imaginary illusion. The term *real* refers to the temporal and material dimensions of gameplay, the passage of time, and the stimulating progression of the digital simulation. The *symbolic* encompasses the structural logic of the binary code that defines everything in the game and that must be internalized by the player to play successfully. The *imaginary* is the dimension in which the player experiences the game and attributes meaning to it.

The temporal dimension of the real allows us to divide the process of video game playing into three fundamental phases: the learning phase, the fluid phase of gameplay in which the player dives into and focuses in on the experience of playing, and the resurfacing of the player from this intense involvement. Players have to first learn a game's controls and rule system, which are prescribed on the level of the symbolic. The symbolic is the dimension that defines what exists in a given game and which actions are possible within it. A game's events unfold along symbolic chains, series of zeros and ones; everything must be anchored in the program code. Human players can interact with video

games because they partake in the symbolic as well; players always have to interact with the code of a game, engaging its particular system of rules, to act in it. The interactivity of video game playing is grounded in the circulation of symbols between computer and player. Every legitimate interaction is defined in the symbolic order—what Lacan calls “the big Other,” for which he accordingly uses the notation “A” (for French “Autre”) in his algebra of the unconscious (Žižek 1999)—that is defined in the program code of a game. To play, the player must submit to a position that is prescribed by the program and differs from game to game. Success in the game occurs when the player’s actions conform to the demands of the code.

From the perspective of cybernetic psychoanalysis, the player and the computer game form a unit, a “*cyborg*,” which is short for “cybernetic organism” (Haraway 1991). Both participate in the same information circuit and are connected through the interface of the game system, which can be divided into two layers: the invisible symbolic processes and the multisensory contact surface (Pias 2004). The symbolic processes take place within the computer as well as within the central nervous system of the player who has incorporated the rules of a game. They generally occur on an unconscious level—below the level of perception—and perform a twofold act of translation. The series of binary symbols connect the motor input of the player with the multisensory output of the program and create an information circuit in which both participate. The contact surface of the interface normally consists of a screen, loudspeakers, and controller. Players complement the visual, auditory, and

haptic output of the game through their active imagination.

The imaginary is the dimension of the ego and the level on which computer game playing is consciously experienced by the player. On the level of the imaginary—a dimension that computers do not have, only human players—games become meaningful experiences. The series of zeros and ones generate whole worlds that are absolutely meaningless on the level of the symbolic but offer intensely engaging experiences in the imagination of the players. It is common for players to actively imagine themselves in a game world, taking on the identity of their avatar and having highly meaningful experiences. The playful act of pretending is what allows the player to enter into the game world on the other side of the screen. Together, player and program project the game’s virtual reality—understood as the multisensory interaction with data structures—into the realm of the factual. During intense phases of play, the player’s sense of reality is reoriented toward the game world, creating an affective link with the avatar.

Video game playing takes place along an axis of disembodiment and reembodiment. The technological interface disappears during the course of play, and the player dives into the game world—a phenomenon called *immersion*. When a player submits to the rules of a game, *transference* occurs—the psychoanalytical term for the mobilization and actualization of unconscious wishes (Laplanche and Pontalis 2006, 455–462). A player successfully coupled to a video game dives into an illusion that unfolds itself between his or her imagination and the multisensory contact surface of the interface. The visual, auditory, and vibratory

patterns act together with the interactive possibilities of a virtual embodiment to make players forget their immediate surroundings as well as their physicality. Players connect with the role the game offers, and the virtual world becomes meaningful. One way of understanding the relationship between players and avatars is as a process of identification; players enter into a “mirror relationship” with their game figure. The avatar takes the position of what Lacan calls “object petit a”—the external picture that the unconscious self needs to introject to form an imaginary identity (Lacan 2006). And the player partakes in a real process of becoming that identity, whether the avatar is Lara Croft (*Tomb Raider* series), Niko Bellic (*Grand Theft Auto IV* [2008]), or the Zerg swarm (*StarCraft* [1998]) (Deuber-Mankowsky 2005; Butler 2010).

As soon as the controls of a game have been successfully mastered by the player, the experience of *flow* becomes possible, a term coined by the psychologist Mihalyi Csikszentmihalyi (2000) to refer to the phenomenon that an activity, which develops consistently out of itself, can take hold of the person performing the action and carry him or her away. People in this state of mind tend to forget themselves as their thinking and doing merge with each other. Self-reflexive thought patterns tend to disappear in the process of flow, the boundary between symbolic exchange and imaginary experience blurs, and a feeling of total control is experienced. The player’s conscious ego (what Lacan calls “moi”) does not think about which buttons to push; rather, the player’s unconscious self (what Lacan calls “je” [Lacan 2006]) dances with the computer game.

The state of flow only lasts as long as the player is successful. Equally, the immersion of the player and the player’s identification with the avatar is not total; they only exist while the game is running. During gameplay, the player’s psyche oscillates between closeness to the avatar, bordering on symbiosis, and a self-reflective distance that occurs, for example, when a player tries to do something that is not anchored in the code, when his or her virtual embodiment dies, or when the gaming system malfunctions. In such moments, the interface stops being a connecting membrane between computer and player and makes its presence known as a border separating the two. Video game playing is, like every form of play, a schismatic experience that oscillates between the poles of intensive inebriation and reflexive awareness, between self-loss and self-reference (Butler 2010). The complementary experience to the imaginary immersion in a game is the moment when the symbolic underpinnings of the simulation are blatantly obvious. In the real process of gameplaying, the virtual world is alternately perceived as an “imaginary illusion” and as a “symbolic fiction,” to use a distinction made by Slavoj Žižek (1997, 127–141). This doubling of the player into an involved actor and a distanced observer is constitutive for computer game playing, which always ends with an abrupt end of the gameplaying session, whereupon players not only emerge from their imaginary immersion but also become fully conscious of the time spent playing as well as bodily sensations such as hunger, thirst, and eventual aches.

Multiple partial drives are mobilized during video game playing. First, a stimulation of the visual, auditory, and

tactile senses takes place. The conjunction of eye–screen, ear–speaker, and hand–controller are “erogenous zones” (Freud 2000), sources of pleasure, or, rather, “cyberogenous zones,” erogenic zones that are part of a cybernetic loop. In the real rush of computer game playing, desire is invested in the perception process itself (Deleuze and Guattari 2004, 312–313), in the sights, sounds, and sensations of the game world. Second, computer game playing encompasses the desire to show. Players direct the action on the screen and gain pleasure from exhibiting their prowess to themselves and others. Third, the conjunction of hand and controller feeds into the drive for power and mastery. The practicing of the different control combinations to perfection as well as the successful mastering of the game’s scenarios is a great source of pleasure for players. Fourth, the drive for knowledge and exploration is also fundamental for gameplay. Curiosity compels players forward because they want to know how a game will unfold. Finally, the desire for intense experiences is fundamental to gameplay, which always encompasses an anxious pleasure for the players. The uncertain outcome of the player’s moves within the game feed into the heightened vitality of playing and is a fundamental component of all play. Regardless of which of these drives is most dominant in a given game, the libidinous configuration of gameplay strives for the establishment of plateaus, continuously flowing zones of vibrating intensity (Deleuze and Guattari 2004, 24).

Another way of understanding the relationship between player and avatar or, rather, the one between player and game, besides seeing it as identification,

is to conceptualize it as a rhizomatic connection (Deleuze and Guattari 2004, 7); players deterritorialize themselves, dissolving their ego and its imaginary relationships, and reterritorialize themselves in the game worlds they partake in while playing. And the gaming systems they use simultaneously deterritorialize themselves through the multisensory performance of the interface and reterritorialize themselves in the imaginations and the bodies of the players. For example, reports from *SimCity* (1989) players describe how their perception of the non-virtual cityscape changed after playing the game (Butler 2007, 148–149). Over the course of countless hours, in countless repetitions, players imprint the cognitive and sensomotoric structures demanded by the game on their bodies and imaginations. At the same time, players collect experience with the different facets of gameplay and gain increasing competency in dealing with the diverse psychodynamic phenomena described here.

Psychological Research on Video Games

Psychologists have long been interested in the effects of media. Decades before video gaming became the popular form of entertainment it is today, researchers were examining the impact media models had on behavior. In 1961, Albert Bandura conducted his famous "Bobo Doll" experiment. This study revealed that preschoolers who watched an aggressive adult model were two times as likely as the control group to display aggressive play behavior. Bandura's social learning theory (Bandura 1973, 1977) paved the way in linking observation of violent media models on television, and later in video games, to aggressive behavior. A meta-analysis of 136 studies strongly indicated playing violent video games is a causal risk factor for aggressive thoughts, feelings, and behaviors (Anderson et al. 2010). A subsequent meta-analysis of 24 studies aimed to address criticisms of Anderson et al.'s findings (Prescott, Sargent, and Hull 2018); however, results supported the link between violent video games and physical aggression.

Impact of the media on behavior has been a hotly debated topic (Steinberg 2008). There are three theories that can be applied to understanding video game influence and usage. The uses and gratifications approach purports that individuals' preferences shape their video game usage (Katz, Blumler, and Gurevitch 1974). Cultivation theory proposes that the content of video games shapes

individuals' preferences and behaviors (Gerbner et al. 1994). Lastly, the media practice model suggests a reciprocal relationship between individuals' preferences and video game content (Steel and Brown 1995). Most early research focused on the negative impact of video games; however, today, many researchers are examining the benefits of video games.

Adults are concerned with the video game usage of young people. Parents and researchers believe that violent first-person shooting games have negative effects on children's mental health. Numerous studies (such as Anderson and Dill 2000; Bartlett, Harris, and Baldassaro 2007; and You, Kim, and No 2015) show that violent behavior and aggression increases after playing these games. Yet, DeCamp and Ferguson (2017) purport family and social variables moderate the relationship between violent video games and aggression. There is evidence that violent video games do not increase hostility in teenagers but do increase stress levels in girls (Ferguson et al. 2016). Some research supports competitive playing rather than violent content may increase aggression in the short term as well as longitudinally (Adachi and Willoughby 2013, 2016). Other research indicates playing video games for more than one hour a day may increase inattention symptoms, such as those associated with attention deficit hyperactivity disorder (ADHD; Chan and Rabinowitz 2006). In addition to increased hostility and inattention, video game usage has been correlated with obesity and low levels of physical activity (Koezuka et al. 2006). Moreover, it does not appear learning engagement or problem-solving skills gained

from gaming transfer to classroom settings (Hoffman and Nadelson 2010).

As the world becomes increasingly technological, video game usage continues to grow. Many researchers are looking for ways to use video games as tools to enhance mental health. For example, a three-dimensional first-person shooter video game, *Medal of Honor: Pacific Assault* (2004), was used to enhance women's spatial abilities, such as mentally rotating objects, which are cognitive abilities necessary to succeed in science and engineering fields. Feng, Spence, and Pratt (2007) proposed video game training to increase the number of women in these male-dominated careers. For girls, coplaying games with parents may protect against the negative outcomes of aggression and decreased prosocial behaviors and increase family connectedness (Coyne et al. 2011). Research is growing in the area of investigating the utility of video games in autism treatments. Blum-Dimaya et al. (2010) used *Guitar Hero II* (2006) to teach children with autism appropriate leisure skills. Leisure skills are believed to enhance quality of life and allow increased development of social skills, two things important to individuals with disabilities such as autism or intellectual disability. Travers and colleagues (2017) used biofeedback-based video game balance training to improve posture in children with autism. Furthermore, playing video games fulfills socialization needs, such as peer recognition and competitive discussion (Hoffman and Nadelson 2010). Finally, playing active video games (e.g., on the Nintendo Wii) was significantly related to higher levels of physical activity (Leatherdale, Woodruff, and Manske 2010).

Rachel F. Pickett

Q*bert

*Q*bert* hopped into arcades in 1982; it was Gottlieb's fourth game and its only coin-op hit. In the game, Q*bert, a round character with a tubular nose, giving his head a "Q" shape, must traverse a pyramidal playfield one cube at a time, changing the color of the tops of the cubes with every touch, until they are all one uniform color. Released at a time when many arcade games were violent by design, *Q*bert* had an innocent charm. Because the protagonist was unarmed and the playfield was filled with various enemies, Q*bert had to survive by his wits and dexterity.

In the beginning of the game design process, Q*bert shot projectiles from his nose, thus the presence of his extended snout. The working name for the game at one time was *Snots & Boogers*, but it was changed, according to *Q*bert* artist Jeff Lee, because the title was "considered too vulgar for a business in an industry which had always struggled against the taint of disrepute" (Lee and Thomasson 2003).

Cube motifs from the art of M. C. Escher heavily influenced *Q*bert*'s art and design. Escher's *Relativity* (1953) set the stage for the unusual orientation of the characters Wrongway and Ugg as they travel on the pyramid. Similar to the groundbreaking arcade game *Zaxxon* (1982), *Q*bert*'s unique art style features an isometric view that offers a visual representation of a three-dimensional playfield in two dimensions.

The final name chosen for the game evolved during a brainstorming session from the random name "Hubert" and the word "cube," taken from the design style of the shapes that make up the pyramidal playfield: Cube + Hubert = Cubert. The word *cube* was shortened to the letter *Q* for pronunciation, finally arriving at the name for the game, *Q*bert*.

The arcade game's marquee exclaims "@!#?@!," implying that Q*bert is disgruntled. Amazingly, the console speaks its own unique language; the seemingly unlimited vocabulary of Q*bert is actually the machine's synthesizer generating random sounds. Audio engineer David Thiel developed the technique that strung together random phonemes. As a consequence, the machine spits out a different string of gibberish each time the game is played and, on occasion, accidentally creates an actual coherent word.

In the end, approximately twenty-five thousand *Q*bert* coin-op machines were sold (Kent 2001). The game became a household name, and as a result, multiple licensing deals were negotiated. Q*bert could be seen gracing products such as board games, frisbees, lunch boxes, and more. Q*bert even had an animated Saturday morning cartoon, broadcast as part of CBS's *Saturday Supercade*. *Q*bert* was one of the few arcade games to also get a pinball treatment as Q*bert's Quest (1983).

The game spawned an additional arcade title, *Q*bert's Qubes* (1983). Numerous home console and home computer

variations as well as sequels, such as *Q*Bert Rebooted* (2014), were released for dozens of home video game platforms. *Q*bert*'s legacy continues to grow, with the character appearing in the theatrical movie *Pixels* (2015) and Disney's *Wreck-It Ralph* film series.

Qix

Taito's arcade game *Qix* (1981) is a very abstract game, even for its time. The coin-ops' attract mode reads, "Your marker controlled with joystick. To draw stix press fast or slow. Claim areas by joining walls with stix." In its most basic form, *Qix* is a real estate acquisition game, but even that description is vague and confusing. The attract mode continues, "Scores based on area. Fast score 250. Slow score 500. Claim more than 75% of playfield for special bonus." While the player attempts to claim playfield space, the *Qix* tries to prevent such action and is deadly to the touch.

As intangible as the gameplay may seem sight unseen, its name is also just as confusing; it is pronounced "kicks." There are two stories rumored to explain the possible origin of how the game

received its unique name; as with much lore, these should be taken with a grain of salt. The first tale goes something like this: Taito debuted the game at the 1981 AMOA show, the press was on hand for the event, and the game was made available for play to attendees and honored guests. This was the early 1980s, and Atari was on top; therefore, much of the camera eye focused on Atari founder Nolan Bushnell. Rumor has it that he sampled Taito's new game, giving the cabinet "kicks" in frustration as he quickly lost his tokens to the machine. While it is not wholly unusual for a product to be displayed before a product name has been assigned, and while this event is recorded to have happened, it is probably more plausible that codesigner and programmer Randy Pfeiffer, who had his automobile decorated with a vanity license plate stating "JUS4QIX," continued his trend by aptly naming his game the same. This story has been shared by his wife, Sandy (Thomasson 2009).

While maze games and intergalactic battles ruled the early arcades, *Qix* was a breath of fresh air and a shot of originality when it appeared on the scene in 1981. As the first "drawing game," there was nothing like it in the arcades, and it was very much ahead of its time. Unlike Taito's *Space Invaders* (1978), and most Taito games, *Qix* was created in the United States and not imported from the Japanese market; perhaps that is why the game design was so radically different from other games of the time.

Initially, *Qix* jumped to the top of the charts. However, its popularity dropped off as players deemed the machine "simply unbeatable" due to the random and unpredictable movement of the dreaded

Qix. With an enormous number of possible movement combinations and no patterns to fool the Qix opponent, even the best players lost interest when they could not improve their scores and best the *Qix* cabinet.

Qix vanished from the arcades rather quickly after its short but modest success. Most machines were converted to higher-earning Taito titles. The arcade version of *Qix* is a rare find and is becoming more valuable to coin-op collectors and fans alike.

Qix II Tournament (1982) offered an enhanced variant that altered the color scheme. Taito placed *Qix* in a state of dormancy for a half decade until Taito released *Super Qix* (1987) in the arcade to little fanfare. In Japan, another sequel, known as *Volfied* (1989), was released, which was published in North America as *Ultimate Qix* (1991) on the SEGA Genesis and later on the *Taito Legends* (2005) compilation for the PlayStation 2 and Xbox.

Taito also licensed *Qix* for release on the Gameboy (1990), the Nintendo Entertainment System (NES; 1991), the Atari Lynx (1991), the Game Boy Color (1999), and the original PlayStation (2004). *Qix++* (2010) was made available on UMD disc in Japan for the PlayStation Portable (PSP) and was available for digital download on Xbox Live, as well.

Quick Time Events (QTEs)

Quick time events (QTEs) refer to the integration of fast-paced and largely predetermined hand-eye coordination challenges within the confines of a broader ludic system. The gameplay configuration associated with QTEs is strongly evocative of laserdisc-based games emerging in the arcades at the turn of the 1980s, epitomized by the release of *Dragon's Lair* (1983). In terms of challenge, it can also be related to electromechanical novelty games found in arcades and at fairs and more recently to rhythm-and-dance video games. In contrast with Whac-A-Mole variations and *Dance Dance Revolution* (1998), the fast execution challenge associated with QTE segments represents a side attraction within a more complicated game configuration. It is commonly defined as a type of minimally interactive cutscene (Klevjer 2014).

Before the proliferation of the expression "quick time events" at the turn of the 2000s, *Dragon's Lair* often acted as a metonymic generic marker encompassing all games that relied on matching inputs with on-screen signals integrated over lavish animated backgrounds. In terms of structure, these data-intensive assets can be acted out in a strictly linear "fail or pass" type of sequence or in a multidirectional network or directed flowchart. This hypermedia-like architecture was typical of early laserdisc-based games; *Dragon's Lair*, for instance, switched the order of narratively autonomous scenes before leading players to the final confrontation. QTE segments

integrated in *Die Hard Arcade* (1996) and *Shenmue* (1999) tend to follow a less complicated, unidirectional logic in which fail states represent the main variation. The background assets are commonly generated through the remediation of static media such as animation or live-action sequences; even instances built upon real-time 3-D engines, such as those seen in *God of War III* (2010), rely on static motion capture or animations. QTEs represent a way for designers to secure more control over the spectacular execution of action sequences.

QTE-type challenges tend to be associated with a simplification of gameplay that seeks to emphasize pure spectacle. Games that integrate these segments to a large extent have been criticized for their overtly directive nature, especially in the context of action games. Kevin VanOrd singled out the desire to recreate cinematic set pieces in his negative criticism of *Resident Evil 6* (2012). It is common to come across mixed feelings toward companies, such as Quantic Dream and Telltale Games, that try to elevate these configurations, making them one of their main engagement models. However, these studios have refined the QTE formula beyond the “hit the right button at the right time” design to model complicated action sequences. In contrast with a stable repertoire of mechanics, which allows players to tactically engage with a sequence of similar challenges, QTE action mappings introduce greater variety in depicted actions. Moreover, the intensity of the virtual actions can be echoed by cumulative inputs on the manipulation interface: players have to perform a streak of time-critical button-matching operations to complete a complex chase sequence in *Indigo Prophecy*

(2005) or intricate finishing moves in *Asura's Wrath* (2012). QTEs could also be seen as a form of “spectacle reward” that punctuates other challenges with visually impressive segments.

Quraish

Quraish is a real-time strategy (RTS) game with three-dimensional graphics developed by AfkarMedia in 2005. It was designed by Radwan Kasmiya and published by Dar al-Fikr in 2007. The name

comes from “Quraish/Kuraish,” a famous Arabian tribe whose descendants include the Prophet Muhammad (570–613 CE) and the most famous Muslim leaders, the Omayyad and Abbasid caliphs. The game’s story is spread over four historical successive campaigns, covering Middle Eastern history before Islam until early Muslim conquests (600–638 CE), with each campaign consisting of a number of levels. Players must finish each level to play the next one.

The game’s first level, “First Encounter,” depicts life in Arabia before Islam, the first Arabian tribes’ coalition, the defeat of the Persian army at the battle of Dhi Qar in 609 CE, and the appearance of Islam. The second level, “Apostasy Wars,” is the story of the Wars of Apostasy and battles that reformed the Muslim state. The third level, the “Conquest of Persia Campaign,” follows the history of the Muslim conquests in southern Iraq and battles with the Sassanid Empire. The fourth level, the “Conquest of Syria Campaign,” tells the story of Muslim armies sweeping north of Arabia and beating Byzantine armies at the doors of Jerusalem. The narratives of every campaign are performed by non-Muslim characters, allowing players to experience different opinions about Muslim conquest wars. Even though *Quraish* features real historical characters, many top characters were not shown directly due

to the sensitivity of showing images of the Prophet Muhammad and some of his major followers in media across the Middle East.

Players can play fictional and customized death matches, choosing from the main four factions of the game: Arabs, Bedouins, Byzantines, and Sassanids. Recommended system requirements for the game include Windows XP or Vista, a CPU speed of at least 1.8 MHz, 64 MB of VGA memory, at least 512 MB of RAM, and 1.2 GB available on the hard disk. Multiple versions of the game have appeared, including four independent Arabic versions, each of which includes a single campaign, and the Golden version, which includes all four campaigns and English and Arabic interfaces. The game is the first Arab/Muslim strategy game and the first one to handle this period of history.

Radwan (RAD) Kasmiya

R

Race

Race in video games remains a hot topic both inside and outside the gaming industry. With the advent of phenomenally popular game series, franchises, and titles that feature must-play characters (MPCs) and playable characters (PCs) who are racially and ethnically diverse, it is clear that beyond the often rhetorical fever pitch, race matters in video games have undergone significant change. Among those games signaling a veritable paradigm shift in the medium's address of matters of race and difference are *Final Fantasy* (1987), *Prince of Persia* (1989), *Madden NFL* (1992), *Resident Evil* (1996), *Half-Life* (1998), *Tiger Woods PGA Tour* (1999), *Blade* (2000), *Halo* (2001), *Grand Theft Auto: Vice City* (2002), *Call of Duty* (2003), *Grand Theft Auto: San Andreas* (2004), *Men of Valor* (2004), *NBA Ballers* (2004), *NFL Street* (2004), *Afro Samurai* (2005), *50 Cent: Bulletproof* (2005), *Prey* (2006), *Gears of War* (2006), *Saints Row* (2006), *Mass Effect* (2007), *Def Jam: Icon* (2007), *Left 4 Dead* (2008), *Prototype* (2009), and *StarHawk* (2012), among others. Most striking of the notable changes these games share in terms of MPCs are more black, brown, and other minority characters positioned as central narrative agents who factor as essential elements in contemporary gameplay mechanics and strategies, game world designs, and gaming's favored genres that are especially pertinent for today's increasingly global,

multiracial, and multicultural fan bases and intergenerational audiences.

As remarkable and welcome as this shift may be in the larger representational ecology of gaming's changing racial characters and avatar designs, at the same time, it is crucial not to lose sight of how much gaming's most successful narrative conceits and ludic gameplay procedures persist in replicating established and damaging discourses of race and difference so familiar in American popular cultural productions and entertainments such as film, television, and music. In fact, with gaming's growing market share of the larger global entertainment industrial complex, concerns and debates about race and representation in gaming abound, especially online and in digital media's proliferating gaming fora and websites, YouTube videos, and other platforms devoted to games and their rhetorics involving race. In fact, any cursory review of these issues, either online or in print, reveals simultaneously progressive and regressive discourses about race in gaming. If we consider some of gaming's most iconic and emerging lead characters, such as *GTA: San Andreas*'s African American character Carl "CJ" Johnson (the gang member protagonist), *GTA: Vice City*'s Italian American character Tommy Vercetti (the mafia protagonist); and *Prey*'s Native American character Domasi Tawodi (on the iconic side of the racial and ethnic MCP scale) and *Mass Effect*'s Black soldier, Commander John

Shepard; *Men of Valor*'s Black Vietnam veteran, Dean Shephard; *Starhawk*'s Black gunslinger, Emmet Graves; and *Resident Evil 5*'s Black African woman bioterrorism fighter, Sheva Alomar (on the emerging side of gaming's MPC scale), we can grasp what is at stake in debates about gaming's powerful rhetorics where race and representation intersect.

I have argued elsewhere (Everett 2005; Everett and Watkins 2008) that much of gaming's representational economies are drawn from its literary, filmic, theatrical, and fine arts forebears. With whiteness as these media's racial default or norm for heroic character designs, it is hardly surprising that video games follow this successful binary normalization of heroic whiteness and its racial Other in gameplay worlds and ludic practices. So honest appraisals of gaming's redolent discourses of race and difference continue to demand scrutiny and challenge. A key repository for such contemporary critical interrogations is the internet, with its rapidly proliferating websites, blogs, vlogs, and other online fora dedicated to games.

Exemplary in this regard is "Moving Forward on Race in Games: Manveer Heir Speaks," an online article in which gaming journalist Brandon Sheffield conducts a revealing interview with Heir (a major game designer with Raven Software and BioWare). This blunt conversation echoes some key points about race in gaming that I have stressed elsewhere. For instance, concerning the nation's denial of persistent structural racism as a feature of U.S. society and culture, Heir is quoted as saying, "In general, people don't want to deal with race." He continues, "First off, I don't think the game

having a Black character [should] be the selling point of the game. It needs to be an interesting game regardless of the protagonist. . . . So, I think that if you market your game as 'a game for Black people' or 'a game for Asian people,' it is going to flop the same way most of the games for women flop" (Sheffield 2011).

That this game designer views increased racial diversity in gaming's character designs not as tokenism but as central to the medium's future growth, development, and continued success is significant and portends well for new gaming design models and character development. Most striking in contemporary conversations about racially diverse MPCs constituting a necessary industry game changer is the realization that expanding stories and heroic characters, who better reflect all gamer communities and constituents rather than the dominant white male archetype, is simply smart business sense. As Heir puts it, "It's not video game affirmative action. It's about actually pushing our medium to make better games, to tell better stories in our games" (Sheffield 2011).

Not surprisingly, another key consideration that Sheffield and Heir explore is mainstream society's general disavowal or repression of how race and racism in gaming get maintained and manifested in other modes and codes of character differentiation. Heir remarks cogently on the types of race and ethnic displacement occurring in popular gaming narratives, observing, "You can think of fantasy games where the dark elves, you know, the Drow [in *Dungeons & Dragons*' massively multiplayer online role-playing games] MMORPGs, were always looked upon. . . . They were the Black people of the fantasy world, right? And if you

played the dark elves, you were treated like garbage by many of the townspeople. So, my only question is . . . why can't we do that when we're actually talking about real people?" Sheffield gets to the heart of the matter when he acknowledges that game designers, gamers, and others can subvert the issue by resorting to fantasy and alien characters of ambiguous racial origin and background. As Sheffield points out, "It's an easier pill for everyone to swallow because it's like, 'well, I'm not saying this about any person.' It's so ambiguous. People are afraid to make any kind of direct statement about anything" (Sheffield 2011).

Another particularly illustrative case is the phenomenally popular 2001 version of the 1994 *Warcraft: Orcs and Humans* fantasy MMORPG. Rebooted and renamed the *World of Warcraft (WoW)*, here is a transformative game franchise that indirectly engages issues of race and difference, although it foregrounds racial matters directly. After all, its fictional Azeroth game world is populated by an array of fantastic nonhuman MPCs—namely, the Orcs, Trolls, and Dwarves—and their missions entail joining forces with or combating MPC human characters in game quests between the game's warring Alliance and Horde factions. *WoW*'s striking appeal, arguably, trades largely on its not-so-covert racial discourse with Cold War and War on Terrorism militaristic overtones (the Allies versus the Axis). Updated to reflect the post–September 11 war on terror Western response, it is not unreasonable to see *WoW*'s fantasy war genre game universe as a mythological fantasm conjoining U.S. World War II and Cold War mythemes and the twelfth- and thirteenth-century religious crusades

with a bit of colonial Orientalism added to encompass a consumable history of premodern and modern warfare, or a good-versus-evil contest of wills. This is what is so insidious about the codification of race and racial difference in these hugely popular games about race.

We can see similar narrative trends in earlier game titles such as *Donkey Kong* (1981), to cite a classic game exemplar. Clearly based on the film *King Kong* (1933), this beloved game codifies socially agreed-on discourse about Black males' rapacious desire for innocent and helpless white female sexuality. Although no one can miss the fact that Kong is analogous to those African states known as the Republic of Congo/Kongo, one can easily miss the fact that the term *Kongo* in Japanese refers to an indestructible one. That *Donkey Kong* is Japanese game designer Shigeru Miyamoto's creation clearly muddies the issue somewhat. Still, the fact that a gorilla, signifying African-ness or blackness, has captured the white princess who must be rescued by Mario, signifying Italianness or whiteness, patently trades on familiar racial scripts that should not be discounted or ignored. Games, like their narrative progenitors—literature, pulp fiction, theater, radio, and television, for example—draw from a history of racist and racialized narratives and representations that make gaming's procedural rhetoric, to borrow Ian Bogost's useful term, meaningful and intelligible.

Another familiar and abstracted racial script that informs gaming's popular narratives of conflict, death, and destruction is the fantasy character constructs of nonhuman or unhuman zombies, who make perfect evil antagonists for gamers to annihilate reflexively and pleasurably.

And although game zombies may be MPCs as well as NPCs, they are often codified or marked as racially and ethnically diverse and Other, but in the main, they tend to signify racial blackness. Nowhere is this practice more clear than in Capcom's *Resident Evil 5* (2008) with its zombie-like humanoid enemies called the Majini, a Swahili word meaning "evil spirit." This seventh installation of the lucrative *Resident Evil* game franchise stirred up a major controversy because of its blatantly racist depiction of a horde of man-eating black Majini juxtaposed with the heroic white human MPC Chris Redfield and his bad-ass Black human MPC sidekick of African descent, Sheva Alomar, and its setting in some African village. Websites such as GamePolitics.com, WallStreetJournal.com, BlackLooks.org, TheZombiephiles.com, and many, many others had a field day with the controversy when Capcom unveiled its game trailer at the 2007 E3 convention. Apparently, no one was buying the company's good, black, scantily clad babe heroine as a sufficient counterbalance to the horde of bad Black boyz in the jungle to deflect the charges of racism leveled at Capcom and *Resident Evil 5*.

Especially meaningful here are Manveer Heir's honest and informed observations about race and gaming from inside the industry's inner sanctum. Heir, who is of Indian descent, grabs our attention with such telling remarks as this:

I mean, it is an uncomfortable topic, especially in the U.S., where racial issues are always going to be a hot-button issue, from my perspective—just on the way the country was founded, right? . . . While I love plenty of games that use these alien and fantasy characters, I don't even think

they go in saying, "I want to make this commentary on this culture." They're just like, "We have these fantasy characters," and once they've made those races or whatever they have, oftentimes, they just start making parallels to what you see in life. . . . "Well, this race is like this race." You know, "This is the Asian race. Let's do it this way." I think it's actually kind of accidental. I'm not really sure. I haven't been a creator of fantasy worlds, but that seems to be the way it always happens to me. . . . And oftentimes it will feel like an entire race is pigeonholed. (Sheffield 2011)

He adds further, "I don't personally believe your game is going to sell worse if the protagonist's skin color changes and everything else in the game was the exact same. Nothing else changed about the game. All you did was default the white to the black guy [or any other race]—that's the easiest route."

Sheffield and Heir's conversation reflects well the discursive range of expressed concerns about race in contemporary gaming, from activist gaming journalists off-line and online eager to call out racist practices in the industry, to annoyed gaming fans—of all races—ranting and railing against the politically correct benighted fools who see racism everywhere, to the game industry writers and representatives who claim to "be afraid of putting characters of other ethnicities into their games because they don't want to get judged for it by the ethnic groups that they're representing" (Sheffield 2011). On the one hand, perhaps some of the complaints about racism in gaming go too far, and on the other hand, it is absolutely the case that the gaming industry's self-policing tactics do not go far enough to address this very real issue.

Our concern with race in gaming culture is not a trivial matter, far from it. We know that games are particularly adept at teaching all manner of lessons, both serious and innocuous alike. As Ian Bogost points out, games make an argument, “and players unpack that argument through play” (Bogost 2008, 130). What we need to ask ourselves as a society is, “What kind of racial arguments do we want to unpack time and again in the games we play?”

Finally, since Michel Marriott’s groundbreaking 1999 *New York Times* article exploring issues of race in computer games, there has been both progress and retrenchment where matters of race and gaming intersect. It is hardly surprising that discourses of race and difference in gaming have not veered too far from those highlighted in the *Times*, despite the fact that a significantly large fan base for games is constituted by gamers of color. Still, there has been progress in the years since Marriott wrote about the prevalence of high-tech blackface and Orientalism in gaming. Game designers are increasingly integrating their ranks with Black and other minority programmers and game narratives, characters are increasingly racially and ethnically diverse, and games feature many more MPCs in integrated game worlds and universes. At the same time, it is clear that the gaming industry and the gamers themselves need to do better because, after all, playing with race is serious business.

Racing Games

The term *racing games* generally refers to games that provide the player with competitive gameplay using vehicles involved in a race; players compare their speed against other players or non-player characters (NPCs) riding in similar vehicles as opposed to *driving games*, which are more about vehicle control. Because racing games usually have a relatively simple game mechanic and often very intuitive gameplay, racing games were among the earliest video games developed; the first commercial racing games were Atari’s *Gran Trak 10* (1974) and its two-player version, *Gran Trak 20* (1974). The games adopted a top-down view, and their sprites had simple shapes: a series of dots demarcated the racing track, and a rectangle represented the player’s vehicle. The games were released as arcade games and were among the first with read-only memory (ROM) data storage. In the games, the player controls his or her vehicle with a steering wheel, two foot pedals (an accelerator and a brake), and a gear shifter. Another early racing game, Atari’s *Indy 800* (1975), was notable for being the first eight-player arcade game.

At first, the major game platform for racing games was the arcade machine. It was a relatively easy genre to develop because the abstraction and re-creation of the practical experience on which it was based required only a limited

number of simple objects on-screen and no complicated game mechanics. Racing games were the first arcade games to offer a first-person perspective—for example, in *Night Driver* (1976), *Datsun 280 Zzzap* (1976), *Night Racer* (1977), and *Speed Freak* (1978)—making the experience more immersive.

In the beginning of the 1980s, the growth of the game industry and the advent of color display arcade machines served as momentum for the rapid evolution of racing games. The evolution was set off by Japanese game developers; SEGA’s *Turbo* (1981) and Atari’s *Pole Position* (1982) were the first full-blown racing games, providing competitive gameplay and more sophisticated graphics than earlier games. After these two games, the development of racing games was mostly focused on the visual quality rather than new game mechanics. At that time, new advancements in the genre were found in arcade games because of the graphical and interactive limitations of home video game consoles. However, *Revs* and *Enduro* reenvisioned racing games for consoles. *Enduro* (1983), published by Activision for the Atari VCS 2600, had a weather system and leader boards. *Revs* (1984), developed by Geoff Crammond and published by Acornsoft for BBC Microcomputer System, is considered as the first serious driving simulator. Although the graphical quality of the game was not enough to compete with other arcade racing games, the game had realistic game mechanics and a user interface, with various opponent drivers having different artificial intelligence (AI).

SEGA’s *Out Run* (1986), developed by Yu Suzuki, had impressive sprite-scaling graphics and animation implemented by

the best graphic processing technology of the time, improved gameplay, and a force-feedback steering wheel. The game was successful worldwide and showed the future direction of innovation for racing games: better visual effects and more speed. *Final Lap* (1987), developed by Namco and published by Atari Games in 1987 for arcade game machines, was an unofficial sequel to *Pole Position*. In the game, up to eight players were able to participate in a circuit. It had relatively realistic formula machines and detailed depictions of Formula One team identities and billboards. *Hard Drivin'* (1988), developed by Atari Games for the arcade, was the first racing game with three-dimensional filled-polygon graphics. SEGA's *Super Monaco GP* (1989) and Papyrus's *Indianapolis 500: The Simulation* (1990) impressed racing game fans with the sophisticated control mechanics and detailed and splendid visual quality.

In October 1992, Suzuki released *Virtua Racing*, another monumental racing game, which was the first racing game with fully three-dimensional graphics. All objects, including the player's vehicle, were filled-polygon graphics, and the player could manipulate the camera view in the game. In addition, the game realized most of what makes a modern racing game. The game was a huge success globally and significantly influenced the racing games that followed.

Suzuki's next titles included the *Daytona USA* series and *SEGA Rally* series, which improved the game system and visual quality while keeping the basic elements of *Virtua Racing*. The advent of 32-bit video game consoles equipped with an accelerating graphic chipset for three-dimensional graphics, such as the SEGA Saturn and the Sony PlayStation,

served as the momentum of the further evolution of racing games. Because these consoles' technological performance could equal that of arcade platforms, game developers left the declining arcade market and began targeting home systems for their releases. Namco's *Ridge Racer* (1994), ported from the arcade version and released on the same day as the PlayStation, is an early example. After the game's release, most arcade racing games started to be ported to consoles, such as SEGA's *Daytona USA* for the SEGA Saturn in 1995 and Namco's *Rage Racer* for PlayStation in 1996.

By 1997, with the release of Polyphony Digital's *Gran Turismo*, the main platform for racing games had shifted over to home console systems. Since then, the evolution of racing games has been focused on graphic quality and more specialized gameplay for consoles rather than arcade-style gameplay. For example, the *Colin McRae Rally* series deals with strategic and realistic tuning of rally cars, and in the *Project Gotham Racing* series, players can buy their cars and customize them with items purchased using in-game points, which are gained through repetitive gameplay; such gameplay examples were not found in arcade games.

Since the mid-2000s, racing games have been mainly categorized into two subgenres: racing simulators and casual racers. *Racing simulators* refer to racing games that focus mainly on the detailed depiction of cars and environment, vivid weather effects, and realistic gameplay adopting advanced physics engines. The objective of these games is to recreate the driving experience as realistically as possible. With racing simulators, players can virtually experience the driving of their

dream cars. In the gameplay of those games, almost all detailed driving maneuvers are implemented, and the player's driving technique is tested. Also, these games provide the player with very detailed and strategic customization systems, including all interior parts and exterior accessories that influence performance of the car. The best-known examples are the *Gran Turismo* series and the *Forza Motor Sport* series.

Casual racers refer to racing games that mainly focus on easy and entertaining gameplay rather than complicated customization and detailed driving skills. The objective of these games is to provide the player with an exciting experience in a short time. In these games, players can experience skillful driving and exquisite scenery using simple controls without needing to spend much time learning the skills. Also, some casual racers include unique extra gameplay; for example, the *Burnout* series provides crash competitions, whereas in *KartRider* (2004), players can attack other players with various items gained through gameplay. Games in the *Crazy Taxi* series, *Burnout* series, and *KartRider* can be categorized as casual racers.

Reading Video Game Imagery

Video games are a form of visual art and communication, and, as such, they tend to follow certain visual conventions that are often assumed to be understood by the player. Even the mere playing of a game requires certain reading strategies, most of which a player will have picked up from past experience.

First, a player must gain an understanding of the world of the game and its visual space: the dimensionality of the world being represented (which can be two dimensional, three dimensional, or some combination of the two) and the division between the diegetic space of the game world and nondiegetic elements, such as informational graphics (e.g., scores and lives remaining indicators), title screens, decorative graphics, and so forth. Some games, however, play with this distinction, including *Starhawk* (1977), in which attacking ships sometimes shoot away the digits in the player's score, and *Eternal Darkness: Sanity's Requiem* (2002), which deliberately tries to confuse the player as a part of the horror effect it is trying to create (e.g., the game may make it appear that bugs are walking across the screen).

The spaces of the game world, and how to navigate them, must be understood. The player must be able to identify the avatar that he or she is controlling or, in the case of multiple avatars, understand which one is being controlled and how to switch between them. Game world affordances must also be recognized—that is,

which graphics represent the objects, devices, and vehicles that can be used by the player and how they are used. It is necessary to identify other characters and distinguish between those that help and those that hinder, and players must often make such distinctions rapidly. In general, graphical configurations must be read for the player to understand what options and what kind of interactivity are available at any given moment during gameplay.

For games in which navigation is required, how to interactively change the point of view being presented to the player becomes important as well as an understanding of how spaces change as one's point of view changes. Most three-dimensional games construct a standard Euclidean space that behaves similar to the lived-in spaces of the physical world, but games can play with such notions of space and construct counterintuitive structures that players must first learn to identify and then to navigate. Finally, the visual interpretation of the game's spaces and even dimensionality may change during gameplay, requiring the player to learn how and why such changes occur and to recognize them when they do. For example, the graphics in *Echochrome* (2008), *Monument Valley* (2014), and *Monument Valley 2* (2017) require players to alternate between interpreting spatial structures in three dimensions globally (for the turning of structures in three-dimensional space) and interpreting the same structures two-dimensionally locally (points that look like they connect actually do connect, so far as the movement of the avatar is concerned).

As video game graphics grow more complex and experimental, recognition

of such elements as foreground, background, usable objects, passageways, and the avatar may become part of a game's challenge, in addition to all the usual challenges involving speed, timing, and skill. Although well established, the graphical conventions of video games are still evolving, and game designs can always make use of the assumptions they generate to either help players play or make a game more challenging by breaking these conventions.

Reception Theory

Reception theory describes the multiple methods and ways of conceptualizing the interpretative process that occur between text and reader, medium and audience, and, in the case of video game studies, game and player. The concepts of reception theory originate in literary theory and semiotics but have benefited from contributions from multiple fields, including communication, film, media studies, sociology, anthropology, and rhetoric. Theoretical work across these fields provides tools to explain how the sender and receiver of a message co-create meaning through the experience of communication.

For video games, reception theory provides scholars with an ability to explain

how game design (aesthetics, production practices, rules, narrative, etc.) combines with sense making (or ideation) that occurs in the player's mind to create the meaning of the game. Those that employ reception theory typically focus on either an analysis of the "implied reader" found in the game design or the "actual reader" that is documented through empirical analysis of gamers and their gaming context, communities, and explanations of their gameplay. Though the focus and objects of analysis may be different between the two approaches, they are united by their insistence that the meaning of video games is found in the dialog between game design and gamer.

IMPLIED READER APPROACHES

Scholars have often relied on psychological approaches to discover the *implied reader* within video game studies. Efforts to employ these approaches emerged in reaction to the invention of cinema. At that time, religious groups and advocates for censorship believed that movies corrupted the minds of impressionable audiences. In some extreme cases, mass media texts were blamed for race riots. Researchers thought that the movies, through their unique viewing experience and immersive narrative continuity, positioned audiences to adopt the perspective of the implied reader and inspired lewd behavior. Similar reasoning generated claims that video games were responsible for the violent shootings at Columbine High School in 1999 and at Virginia Tech University in 2007. In both cases, pundits and politicians looked to blame media companies for human tragedies.

Analysis of the implied reader of video games can be illuminating for its ability

to explain the structural realities of gameplay. Elizabeth Evans's research (2016) on the implied reader of mobile device casual games is one example of an exceptional study. Evans describes how the games are designed to make the game players "impatient" as they attempt to "level up" throughout the game. The psychology of the game attempts to provoke anxiety in the hopes that gamers will pay money to avoid delays and relieve the tension. Though the implied reader of the game is "impatient," Evans points out that "these strategies are not dictatorial and can be circumvented (Evans 2016)." Her acknowledgment of the difference between the "implied reader" and the "actual reader" is a key distinction that is often ignored when cultural critics attack the psychology of video games. For example, Lieutenant Colonel Dave Grossman and Gloria Degaetano provided a link between violent video games and behavioral conditioning. Grossman and Degaetano have argued in their book *Stop Teaching Our Kids to Kill* (1999) that the experience of playing a first-person shooting game is similar to the experience of military training. Claims like this, although helpful for politicians and censorship groups, assume that all audiences identify with the implied reader. Focusing too harshly on the implied reader often ignores the more complex social and cultural meaning-making that occurs with video games.

ACTUAL READER APPROACHES

Studying the *actual reader* in video games means employing the methods of sociology and ethnography. The emphasis on sociological factors for reception theory

began with the establishment of the first sociology department at the University of Chicago in 1892. The early research of the Chicago School looked at social groups, such as urban juveniles, and attempted to understand how media texts reinforced or mediated their social interactions and community standards. Explaining the function of media within a social group became known as *functionalism*. Video game research still relies on this concept when considering the social interactions between groups of players in massive multiplayer environments and other gaming communities.

In England, in the late 1960s, the Birmingham School of Contemporary Cultural Studies inspired a paradigm shift through the work of Stuart Hall, Richard Hoggart, and E. P. Thompson. The research from these scholars was largely a reaction to the Frankfurt School and focused on individuals and small groups that actively used mass culture as part of their everyday lives. Research on these groups demonstrated that audiences made informed, even political, decisions about their cultural choices. Hall showed that audiences use cultural objects in ways that the producers of those objects never intended. Using the language of semiotics, he described a process of encoding/decoding in which a cultural object, like a video game, is first created with a particular ideological framework and then received in an ideological context that is further contextualized by the receiver's cultural experiences.

One area where this approach has been fruitful is in analysis of the use of casual games in social settings. In interviews and observations that document when, where, and how gamers play mobile casual games, Stephen Rea (2017) has

demonstrated how this gameplay fits within Korean “mass play culture.” By analyzing the *actual reader* of casual games, in a specific context, Rea complicates established perceptions about socializing and gameplay. In Rea's study, the context of gameplay, waiting for friends, commuting, or killing time while in line, reframes the structure of casual games. The “punctuatedness” of casual games, which Evans has argued is designed to create “impatience,” is recontextualized to make casual games a relief from boredom and the opposite of anxiety-inducing. Furthermore, the game design correlates with Korean gaming and socializing traditions, making casual games a sophisticated form of social gaming in the country. In both examples of research on mobile casual games, the scholars acknowledge both the implied reader and actual reader as equal parts of the meaning-making process. Applying reception theory is an effort to account for this fascinating dynamic.

Reddy, Siobhan (1979–)

Siobhan Reddy is a South African-born game designer working in the United Kingdom. She is best known for her work on *Little Big Planet* (2008) at Media Molecule, where she serves as studio director.

Unlike many game creators in the industry, Reddy did not come to the industry already a gamer. Rather, her creative energies were honed in the independent music scene, film, and fanzines. When she was eighteen, she packed up

her life in Australia and moved to the United Kingdom, where a friend suggested that she enter the game development industry. Her first opportunity opened with a position as a production assistant at Perfect Entertainment, the company that created Terry Pratchett's *Discworld* games. From there, she moved to Criterion in 1999, where she worked on the *Burnout* franchise, and then left to cofound Media Molecule in 2006, launching *Little Big Planet* and *Tearaway: Unfolded* (2015). *Little Big Planet* won multiple awards on release as a physics-based puzzle platformer; people could play the game, create their own levels, and share created levels with others.

The success of Media Molecule highlighted Reddy in the game industry, and she took her newfound fame to advocate for more women in the game development industry. She notes that in her early years, she worked with strong women leaders at both Perfect Entertainment and Criterion, which shielded her in some ways from the gender disparity of the industry. In 2013, the BBC named Reddy one of the 100 Most Powerful Women in the UK, and the same year, Qantas named her Australian Woman of the Year, which Reddy read as a call to use her visibility to advocate for women in game culture and development. This call was strengthened by her involvement on the BAFTA Games Committee, where she analyzed the statistics on women in games. Games, believes Reddy, is the quintessential medium of our time and thus should be a place for everyone.

Reddy's work in game development and as a game advocate has also earned her recognition and awards from Microsoft Women in Gaming (2009), *Fortune*

magazine's 10 Powerful Women in Gaming, and installation in the UK Women in Game Hall of Fame.

Remediation

In their book *Remediation: Understanding New Media* (1999), Bolter and Grusin define *remediation* as the process whereby one medium imitates another. New media usually hope to heighten their level of immediacy (also referred to as *medial transparency* or *realism*) by imitating the representational affordances of older media that have already been socially accepted as transparent (54–55). In addition, they attempt to borrow the cultural capital of more established media (69). Although immediacy seems to be the main driving force behind remediation, some media use remediation to highlight the mediated nature of the representation. The two authors call this latter effect *hypermediacy* (31).

Media are enmeshed in a network of remediation, which entails a new medium emerging from already existing ones. Video games are no exception, as evinced by the relation between one of the earliest gaming platforms accessible to the general public, arcade games, and their predecessors, electromechanical games.

The relation between the two ludic media faithfully reflects the promise of betterment that lies at the heart of remediation. Arcade games imitate the format of electromechanical games (devices with a front control panel and a physical game world behind a transparent screen), but at the same time, they solve many of the issues characteristic of electromechanical games, such as the need to be operated mechanically and to be reset between play sessions as well as their difficult maintenance (Wolf 2012, 184–185). Arcade games also offer more functional gameplay activities, such as shooting and racing, than electromechanical games did.

Nevertheless, video games are not a fully interactive medium. Arcade games and, later, console games feature many noninteractive interludes that link together different levels or stages, offer ludic reward, and often serve a narrative function (Blanchet 2012, 151). These noninteractive moments are called *cutscenes*, and they rely on the remediation of other media, such as film, photography, text, comics, and television. Some of the earliest cutscenes can be found in *Pac-Man* (1980) and *Donkey Kong* (1981), and since then, they have appeared in video games across platforms. In the 1980s, the complexity and length of cutscenes depended on the storage capacity of the read-only memory (ROM) used by the platforms. Nintendo Entertainment System (NES) games, whose ROM cartridges offered developers little space, featured minimal, static and text-based cutscenes with no voiceover (Klevjer 2014, 302), while laserdisc games, benefiting from more storage capacity, used a significant length of realistic prerecorded video

during gameplay. As a result of the cinematic nature of the prerecorded content, these latter games displayed a higher level of verisimilitude, which made them similar to feature films or animation. Laserdisc games fall under two categories: either action games with computer-generated content (e.g., playable entity, enemy characters, ludic objects) on top of prerecorded cinematic content (see, e.g., *Astron Belt* [1983]) or games that feature a branching narrative, as exemplified by *Dragon's Lair* (1983) (Wolf 2007, 99–100). *Dragon's Lair* used hand-drawn animated pre-rendered cutscenes that amounted to a length of twenty-two minutes. These animated cutscenes were played back by the arcade game, depending on whether the player managed to press the correct direction or attack button at the right time (Perron 2007, 128). Due to their minimal player involvement, the little variation between different game sessions, and the strong feeling of authorial presence, these games were also called *interactive movies*.

In the 1990s, the popularization of CD-ROMs enabled console and computer games to raise their cutscenes to higher cinematic standards (Klevjer 2014, 302). One type of cinematic interlude that CD-ROM games featured was the live-action cutscene, which used real actors on real sets or on green screens that were played back at plot bottlenecks (Blanchet 2012, 152–153; Egenfeldt et al. 2008, 181). Live-action cutscenes were most common in the interactive movies of the early 1990s (see *Night Trap* [1992], *The 7th Guest* [1993], *Under a Killing Moon* [1994], and others) (Perron 2007, 129), but they were also featured in other games of different genres, such as the real-time strategy (RTS) game *Command*

and Conquer (1995) and the survival horror game *Resident Evil* (1996).

The introduction of 3-D-rendering technology in video games brought greater verisimilitude to cutscenes, making them more cinematic, and game developers could also use game engines to produce the cutscenes in real time rather than pre-rendering them. Games such as *Metal Gear Solid* (1998) and *Silent Hill* (1999) made extensive use of pre-rendered cutscenes in an attempt to imitate the visual aesthetics and narrative affordances of cinema. Moreover, besides remediating film in their cutscenes, 3-D rendering made it possible for games to use more cinematic conventions during gameplay as well. The aforementioned *Resident Evil* and *Silent Hill*, as well as most other survival horror games of the 1990s and early 2000s, employed a variety of cuts and fixed angles during gameplay (Rouse 2009, 23). However, this overuse of cinematic language ended up undermining the realism of the video games and, in turn, led to hypermediacy.

The advent of 3-D rendering in video games brought the intermedial relation between games and cinema to a new level, but it also paved the way for other strong intermedial bonds. The first-person shooter (FPS), a hallmark genre of video games, was an attempt of action games in the early 1990s to imitate the representational and simulational affordances of virtual reality (VR) (Pinchbeck 2013, 18). Despite the fact that VR gear was almost inaccessible to the average user, VR was regarded as an immersive ideal. Consequently, by employing a subjective camera that could be freely moved into any direction, 3-D-rendering technology enabled FPSs such as *Wolfenstein*

3D (1992) and *DOOM* (1993) to imitate VR, at least partially, and to provide players with a level of realism higher than earlier 2-D side-scrolling shooting games.

The subsequent progress of gaming platforms after the 2000s means that most triple-A games have their cutscenes rendered in real time, as you play, by the game engine. Real-time rendering has allowed game designers to make cutscenes more interactive, either through quick time events (as in the *God of War* series) or through control, albeit restricted, of the camera (as in *Metal Gear Solid 5: The Phantom Pain* [2015]). In doing so, game developers have managed to blend together cutscenes and gameplay in a more seamless manner and, consequently, have made a step forward in offering players a more immersive gameplay experience (Klevjer 2014, 303).

Film is not the only medium whose remediation has led to games' attainment of a high degree of narrativity. As Henry Jenkins observes, one of the means employed by games to convey stories is the embedded narrative that consists of the sum of remediated documents scattered around the game world (Jenkins 2004, 126). By finding and reading or viewing these documents, players piece together the backstory of the events in which they are enmeshed. These documents remediate a variety of media, such as letters, diaries, voice mails, e-mails, photographs, paintings, VHS cassettes, and more. The fact that in many cases we are dealing with the remediation of analog technologies is not arbitrary; through such remediations, video games try to borrow the sense of materiality characteristic of analog media and,

consequently, to convey "a sense of real perceived as lacking in digital media, yet central to a generically-significant impression of embodiment" (Kirkland 2008, 115). A good example of this use of remediated analog media is the CD-ROM adventure game *Myst* (1993), whose network of analog remediations is constitutive of the game's story, which the player unravels by exploring game space.

Although video games, comic books, and manga have always been involved in exchanges of narrative content (Picard 2007, 297), games have been reluctant to imitate their aesthetics to the extent that they have done with films and VR. There are, nevertheless, a few noteworthy exceptions in the gaming industry (Hanson 2012, 128). One of the earliest uses of panels and speech balloons can be traced back to the Apple II adventure game *Accolade's Comics* (1987), in which the challenge for the player is to select the right answer in the speech balloons during some moments of gameplay. Another game that remediates comics is *Comix Zone* (1995), a beat 'em up game released for the SEGA Genesis, in which the playable character must move from one panel to another to defeat his adversaries. The game makes complete use of the conventions of comics in that the dialogue is rendered in speech balloons, the narrator's input is provided in yellow captions in the upper left of the screen, and onomatopoeic sounds are rendered in different fonts. In the case of 3-D games, the most prominent cases of comic book remediation are the games *Max Payne* (2001) and *XIII* (2003), whose scripted narratives are delivered through cutscenes that represent comic strips.

Television is yet another medium whose form has been less present in video

games, despite the circulation of content from video games to TV (and vice versa) (Picard 2007, 298). Some games have adopted the episodic nature of TV series. *Resident Evil: Revelations* (2013) structures the narrative of its levels as episodes that end with cliff-hangers, and there is a recapitulation of the previous events at the beginning of each new episode. Other recent video games, including *Life's Strange* (2015), *Resident Evil: Revelations 2* (2015), and *Hitman* (2016), have been released episodically at intervals that range from one to two months.

Video games have also been the object of remediation. Throughout the years, cinema and video games have developed a strong intermedial bond, with films sometimes remediating video games. This is most conspicuous in video game adaptations that, besides adapting the games' narratives to the linearity of film, also try to imitate the visual representation of particular game mechanics. For example, the feature film adaptation of *DOOM* (2005) remediates the first-person perspective of the game by employing subjective camera in long takes that show only the protagonist's weapon. Another video game adaptation, *Max Payne* (2008), uses a variety of filters and special effects to represent the iconic bullet-time mechanic of the game. In addition to this, video game aesthetics have crossed the boundaries of video game adaptations and can be found in films relying on other sources. A relevant example in this respect is *The Expendables 2* (2012), where the representation of headshots strongly resembles that of video games.

The cultural capital enjoyed by video games has led to their canonization. Games that were regarded as mere

entertainment products upon their release are now classics that must be made accessible to newer generations who are unfamiliar with the games or their respective gaming platforms. One of the earliest cases of self-remediation can be found in Cyan's 1990 *Cosmic Osmo*, whose game world contains two arcade games, *Ship Chip Lander* and *RubberGut*, as well as a reference to itself on a monitor (Wolf 2011, 25). Other instances of games remediating other games can be found in *DOOM 3* (2003), *Metal Gear Solid 4: Guns of the Patriots* (2008), and *Uncharted 4* (2016), in which the players can play earlier games indirectly, via the avatar, on old gaming platforms that are diegetically present in the game world. For example, during *Uncharted 4*'s "Chapter 4: A Normal Life," the player controls Nathan Drake, who is playing *Crash Bandicoot* (1996) on the PlayStation. This remediation functions as a diegetic foreshadowing and ludic tutorial for a chase sequence that will occur later in the game. In a manner similar to the remediation of film at the turn of the millennium, by remediating older canonical games, new ones borrow their cultural capital and construct a tradition that lends them legitimacy.

Replay and Repetition

Replay and repetition function as core gameplay elements in most video games, including helping the player to learn play mechanics of a given game and extending a game's long-term play value by allowing for predictability and variability between multiple game sessions. Aspects of repetition in gameplay predate video games; nondigital games often place an emphasis on the player's replaying of a game as a means of learning the rules of play. However, video games often emphasize aspects of repetition and replay even more than traditional games for a number of reasons beyond those of traditional games, including using high scores to encourage mastery of a game through its repeated play and rewarding players who replay a level or entire game after they have been successfully completed. More recently, some video games have begun incorporating aspects of repetition into their gameplay mechanics by allowing—and even requiring—the player to manipulate the passage of time within their structures, further emphasizing replay.

Traditional games such as basketball and chess often require players to play them a number of times to fully grasp the rules and play mechanics of the game. Each time a player replays a game, he or she may learn new rules or more effective play strategies that will help him or her to become a more effective player. Game theorists, including Jesper Juul, refer to games as *state machines* (a term taken from computer science) to help describe the changes in state that are essential to the play of games. For example, each time a player performs an action, such as moving a piece in chess, the game's state transforms because the other player's possible moves may change; for instance, the first player's move may block potential movement of the second player's pieces. Board games particularly emphasize replay because it is possible to replay the exact same events if the same moves are made each time; in chess, for instance, two players may reproduce a famous historical match by making the exact same moves as were made in the original game.

Almost all video games similarly emphasize their repeated replay to help the player learn their play mechanics. Early video games introduced entirely new modes of play by requiring players to manipulate an interface, such as a dial or joystick, to control a sequence of events on an electronic screen. Games such as Atari's *PONG* (1972) also featured few, if any, instructions to help the player understand their rules and effective play strategies. Video games often require skillful manipulation of game elements, such as moving the paddle in *PONG* to bounce a ball to score points and complete game levels.

A first-time player of a coin-operated game is likely learning many of that

game's play mechanics through the process of playing, and thus the possibility of player frustration may be high because the player may be unaware of how the game operates and thus might make repeated mistakes. The designers of arcade games must balance this potential frustration with the need to generate revenue by encouraging players to continue to deposit coins in the machine; game companies adopted the industrial strategy of often giving the player a set amount of time or a few tries, or *lives*, in which to play the game. This allows players to make mistakes while learning the game but still continue to play, thus allowing the player several replays of a game in each game session. Video games such as Midway's *Ms. Pac-Man* (1981) reward players who achieve specific point scores with an additional life within the game, providing another opportunity to replay the game.

Replay is also emphasized in video games by requiring players to observe and learn patterns of movement to successfully complete levels within the game. Platform games (also known as *platformers*) such as Nintendo's *Donkey Kong* (1981) and *Super Mario Bros.* (1985) oblige the player to maneuver through increasingly complex levels, avoiding obstacles and jumping between platforms to successfully complete a level. Through these core gameplay mechanics, players must learn the patterns of movement of enemy characters and features of the game levels through processes of trial and error. These games thus emphasize the repeated replaying of game levels (and portions thereof) to gain a degree of familiarity over their associated patterns of movement for their successful completion. Because the enemies and patterns of

movement in platform and other similar games are often preprogrammed, players may memorize or preprogram controller inputs on a computer to complete a game in as brief a time as possible and share videos of these *speedruns* with other players. This mastery based on repetition rewards players through replay much like a high score table, albeit offering players new modes to challenge other players in communities built around the repeated play of specific games.

Some home video games may encourage players to replay the entire game after its successful completion by offering players incentives, such as new costumes, equipment, or abilities for their avatar, that were not available on the first playthrough of the game. Silicon Knights' *Eternal Darkness: Sanity's Requiem* (2002) prompts the player to replay the game several times, rewarding the player in each iteration with more of the game's backstory before revealing the "true" ending of the game after several such playthroughs. Much like the economic strategy of arcade games offering players several lives, this encouragement to play through a game that a player has purchased increases its *replay value*, a term used by game reviewers, marketers, and consumers to assess a game's potential for continued play value after its completion. Games may also increase replay value by randomizing level layouts, objects, and enemy characters encountered each time the game is played, essentially creating new game situations or scenarios with every session of gameplay. For example, the game *Rogue* (1980) was first developed for computer mainframes by Ken Arnold, Michael Toy, and Glenn Wichmann and employs simple graphics based on the

symbols found in character sets common to computer systems to represent the player, dungeon maps, and various creatures and objects. Each game session of *Rogue* randomly generates these map layouts and elements, creating a unique game experience each time. Named for the play mechanics inspired by this game, the genre of *rogue-like* games features randomization of game elements, such as procedurally generated levels and permanent death (or *permadeath*), wherein the death of a player-controlled character is irreversible.

More recent temporal navigation or temporal manipulation games such as Ubisoft's *The Prince of Persia: The Sands of Time* (2003), Number Nine's *Braid* (2008), Dontnod Entertainment's *Life Is Strange* (2015), Remedy Entertainment's *Quantum Break* (2016), Superhot Team's *Superhot* (2016), and Askiisoft's *Katana Zero* (2019) require the player to rewind, slow, or similarly manipulate time while playing and incorporate replay to correct mistakes and solve puzzles to successfully complete them. Such games use replay as a core mechanic of the games themselves, further emphasizing forms of repetition within video games.

Although replay and repetition have long functioned as key aspects of learning and mastering all forms of games, they play a central role in an increasing number of video games and the ways in which they are enjoyed, experienced, and shared by players.

RePlay Magazine

RePlay magazine is a trade magazine that covers the out-of-home amusement and family entertainment industries. Eddie Adlum founded *RePlay* in 1975, after leaving his position at *CASHBOX Magazine*. (*CASHBOX* covered the music and coin machine industries in the United States from 1942 to 1996, relaunching as a web-only publication in 2006.) *RePlay* began publishing monthly in October 1975, and the magazine’s name was selected because it bore meaning for the jukebox industry and the amusement industry and because it is a pun on “regarding play.”

RePlay’s subscription base peaked at sixty-five hundred during the video game boom of the early 1980s. It declined with the coin-operated video game industry, and eventually settled at a subscription rate roughly half that during the boom. Most copies of *RePlay* are sent to subscribers in the United States, with just a tenth shipping internationally.

RePlay targets business owners who have a vested interest in industry news; the readership includes operators, arcade owners, and game manufacturers and distributors. Types of amusements covered by *RePlay* include coin-operated video games, pinball machines, crane machines, jukeboxes, pool tables, and others.

Historically, *RePlay* has covered numerous emerging trends of interest to its readers, including the automated teller machine (ATM), the addition of upscale attractions to family entertainment centers, and, of course, video arcade games. As a trade journal, the focus of *RePlay* is directly shaped by shifts in the industry and often responds to trends or perceived threats, ranging from legal regulation to moral concerns. Coverage in the magazine generally includes corporate profiles, interviews with game company executives, notices of relevant court cases, and challenges to the amusement industry as well as editorial responses to public issues. Regularly included sections of the magazine include a news section, “Hot Off the Press!”; a chart of the most played games called “Players’ Choice”; and classified ads for the sale of used machines labeled the “Buyers’ Bulletin.”

RePlay publishes several special editions a year, such as the ASI (Amusement Showcase International) issue, the

AMOA (Amusement and Music Operators Association) Expo showbook issue, and an annual industry directory. Back issues of *RePlay* often include editorial responses to contemporary issues of concern to arcade owners and operators. City and state efforts at governing distribution of and access to video games have received significant coverage, as have official statements on the value of video games. *RePlay* has responded to legal battles faced by the industry and has also offered responses to negative publicity from major figures such as U.S. surgeon general C. Everett Koop and President Ronald Reagan.

Although *RePlay* has and continues to cover a wide range of amusements, during the late 1970s and early 1980s, it included extensive coverage of coin-operated video games. In the years directly preceding the industry crash of 1983, the bulk of the articles addressed the video game industry. Since the crash, *RePlay* has continued to offer significant coverage of coin-operated video games. The magazine is particularly useful for those interested in the marketing and distribution of coin-operated games. *RePlay*'s corporate profiles can also be helpful in identifying key players in the production of certain games, many of which have partial credits, if any credits are available. *RePlay* magazine is headquartered in Tarzana, California.

Representations of Video Games in Hollywood Cinema

As video games have become increasingly popular in American culture and the industry has established itself as a major contender for media audiences and the financial capital they wield, they have progressively influenced and appeared within the narratives of Hollywood films. Since the 1970s, filmmakers of both major blockbusters and smaller films targeted at niche audiences have incorporated the visual style of video games into their films, constructed narratives specifically representing video game and arcade culture, and utilized the concept of virtual worlds to inspire both utopian and dystopian science fiction fantasies. Hollywood filmmakers have also adapted individual games and game franchises into films and used the play of specific video games to situate their stories within a cultural milieu unique to the time period of film production.

While video games have appeared in Hollywood films since the early 1970s, with *Computer Space* (1971) being played by a character in *Soylent Green* (1973), multiple histories highlight Walt Disney Productions' *Tron* (1982) as the first major crossover between video games and high-concept Hollywood filmmaking. *Tron*'s narrative revolves around computer programmer and game designer Kevin Flynn (Jeff Bridges), who, due to corporate maneuvering and intrigue within the software manufacturer ENCOM, now manages a game arcade after witnessing the video games he designed being wrested from his control. As Flynn attempts to hack into the ENCOM security system, ENCOM's

nefarious Master Control Program digitizes and transports him into the company's computer mainframe, where he must actively play his own games against his ENCOM adversaries from within the system itself. Not only does *Tron* position the protagonist as an enthusiastic video game programmer and a talented game player, but it also features computer-generated imagery that replicates the visual style of games from the time period—most notable in the Light Cycle race that opens the film—foregrounding bravura digital visuals that evoke the vector graphics common in many early video games. While the Light Cycle race specifically replicates racing games, other sequences, such as a battle in which Flynn must target and evade airships through a heads-up display during close-quarter combat, reference other game genres popular at the time, in this case vector-based shooting games such as *Battlezone* (1980). In *Tron*, Flynn's proficiency at actual video game play and knowledge of game design allow for his successful negotiation of a digital game system within which he is truly immersed, resulting in the narrative's triumphant conclusion.

Importantly, the game company Bally/Midway adapted *Tron* into a successful arcade game in 1982, recasting the film's game sequences, such as the Light Cycle race, into a series of increasingly difficult levels. This arcade game appears in Disney's sequel to the original film, *Tron: Legacy*, released in 2010; Sam Flynn (Garrett Hedlund), Kevin Flynn's son, enters the virtual world his father created through the latter's dilapidated video game arcade after finding his laboratory hidden behind *Tron*'s arcade cabinet. Visualizing decades of change in video

game graphics and genres since the initial film's premiere, set to a throbbing electronic soundtrack by Daft Punk, and released theatrically in IMAX 3D and Dolby Digital 3D, *Tron: Legacy* depicts Sam Flynn's fight to free his father, again played by Bridges, from his virtual doppelgänger, Clu (also Bridges). Through highly choreographed martial arts showdowns, projectile-focused arena battles, and spectacularly explosive Light Cycle races, the obvious advancements in computer-generated imagery and the dynamic use of 3-D in the film are a stark departure from the vector graphics of the original film—and game—while also being an homage.

Although *Tron* is certainly an inarguable touchstone in the history of Hollywood's representation of video games, the incorporation of the computer graphics common to arcade games in major Hollywood films, and the virtual worlds they signify, predates *Tron*'s 1982 release. In George Lucas's groundbreaking *Star Wars*, released by Twentieth Century Fox in 1977, both the Rebel forces' three-dimensional map of the Death Star and the piloting system Luke Skywalker (Mark Hamill) and other X-wing pilots use to aid their attack on the imperial fortress evoke the wireframe graphics of vector games that were introduced that same year. The targeting system specifically implies the visual construction and functionality of arcade shooting games, and the appearance of the on-screen display, coupled with the joysticks and push-buttons the X-wing pilots use to maneuver their small spacecraft as they near the Death Star's single weak spot, brings to mind the interfaces of early arcade cabinets and the design of early arcade games. Similarly, the opening

credit sequence of Disney's *The Black Hole* (1979) is composed on a three-dimensional vector display grid that maps the descent into the titular spatial anomaly that is the focus of the film's entire narrative. Although not overtly referencing specific video games themselves, these spectacular, digitally constructed sequences from 1970s Hollywood films emphasize the visual style of many arcade and home console-based games of the time, uniting a fidelity to the period's game graphics with narratives revolving around interstellar warfare, itself the narrative basis of such games as *Spacewar!* (1962), *Space Invaders* (1978), and *Galaxian* (1979).

Much as *Tron* situated a video game designer as the hero in a war against both malicious software and corporate intrigue, Hollywood films of the early 1980s positioned youthful video game players as protagonists fighting powerful enemies. Teenager David Lightman (Matthew Broderick), the central character of John Badham's popular film *WarGames* (1983), is both a computer hobbyist and a game enthusiast; when not hacking into his high school's server with his IMSAI microcomputer and modem to alter his own grades or those of Ally Sheedy's Jennifer, Lightman plays the digital games he encounters on early local area networks (LANs) and servers. Accidentally engaging a U.S. Air Force supercomputer, known by both the acronym WOPR (War Operation Plan Response) and the code name Joshua, in a game of "global thermonuclear war," Lightman must break into an air force base to prevent the beginning of World War III. Unable to hack into the supercomputer and gain control directly, Lightman instead engages the computer

in a digital game of tic-tac-toe, thus teaching the computer the concept of a stalemate from which neither side can win. Averting a nuclear holocaust through a children's game, *WarGames* contrasts the video games increasingly present in early 1980s suburbia with the Cold War, a potentially devastating game of political posturing and military strategy. The film professes a fear that intelligent machines and their programmers, in control of the United States' nuclear stockpiles, are ignorant of the real-world consequences of their actions, although it nonetheless positions a video game player's ingenuity as the solution to global annihilation.

During the 1980s, Hollywood's willingness to represent video games, and specifically arcade culture, became increasingly prominent. *The Bishop of Battle* (the third in a series of four short films released theatrically as the horror anthology *Nightmares* in 1983) and *The Last Starfighter* (1984), although eventually conforming to the respective genres of horror and science fiction that structure their narratives, feature protagonists who obsessively play arcade games. *Battle*'s J. J. Cooney (Emilio Estevez) hustles arcade attendees in downtown Los Angeles by downplaying his own gaming skills, and *Starfighter*'s Alex Rogan (Lance Guest) escapes the travails of family and trailer park life by playing the only arcade game that stands outside the trailer park's office, aptly titled *Starfighter*. Both teenage boys with exceptional gaming skill, Cooney and Rogan are also similar in that issues of familial domesticity trouble their lives, as Cooney's beleaguered parents worry about his declining grades and Rogan must continually negotiate his

role as the oldest child in a single-parent household. Both *Battle* and *Starfighter* represent video game players similarly, but their narratives bespeak opposing views on video games' effects on youth culture. In *Starfighter's* science fiction narrative, Rogan becomes a celebrated intergalactic hero because of his gaming proficiency, whereas *Battle's* horrific cautionary tale leaves Cooney trapped within the very video game he champions.

The debate over the potentially deleterious effects of video game play on youth culture is indeed the narrative foundation of the 1980s teen sex comedy *Joysticks* (1983), in which a video game arcade becomes the focus of a political battle waged between the arcade's teenage owner, Jefferson Bailey (Scott McGinnis), and upstanding parent-activist Joseph Rutter (Joe Don Baker). Aside from the less-than-subtle sexual innuendo that infuses the film, from the title itself to the conflation of video game "scoring" with sexual proficiency, *Joysticks* creatively depicts the generational divide palpable to youthful video game enthusiasts during the 1980s, particularly in a humorous subjective sequence that contrasts both Bailey's and Rutter's fantasies about the unmasked video game arcade. Whereas Bailey fantasizes about a venue of youthful freedom, sexual liberation, and self-expression, Rutter fears a hellish, shadowy den of moral vice. Even the editing of *Joysticks* is overtly inspired by video games, as the transitional wipes that separate the film's individual scenes are of an intrusive yellow orb, clearly resembling Pac-Man, eating its way through the mise-en-scène.

Video games both inspired Hollywood's science fiction fantasies and

influenced the teen sex comedy and cautionary horror genre during the late 1970s and early 1980s, but they also appeared in films to situate the viewer within a film's narrative world. Watching a character play a particular video game could speak volumes about his or her interests, socioeconomic status, and favorite hobbies. Rob Reiner's self-aware swashbuckling fantasy *The Princess Bride* (1987) opens with a screenshot from Accolade's *Hardball* (1985) for the Commodore 64, which is played by Fred Savage during the film's opening sequence. The on-screen virtual world contrasts strongly with the literary world Savage's character discovers in the pages of a book ("When I was your age, television was called books," says the character's grandfather, played by Peter Falk), and the opening shot of the video game works to define Savage's character as hip, computer savvy, and upper middle class, as he has both a game system and television in his spacious bedroom.

Other examples of video games situating film characters include the montage sequences that establish a romantic relationship between Daniel Larusso (Ralph Macchio) and Ali Mills (Elisabeth Shue) in *The Karate Kid* (1984), all of which take place at the local high school hangout, an overcrowded arcade; the continual play of games such as *Double Dragon* (1987), *Rad Racer* (1987), *Ninja Gaiden* (1988), and *Super Mario Bros. 3* (1990) in *The Wizard* (1989), a film that functions as much as an advertisement for Nintendo games and peripherals as it does as a coming-of-age adventure; and scenes of skilled children proficiently playing arcade games in *Toys* (1992) while the villainous General Leland Zevo (Michael Gambon) is unable to distinguish

between the reality of warfare and the designed fantasy of wargames, establishing Zevo as an obsessive and ignorant character.

Although Nicholas Goossen's film *Grandma's Boy* (2006) would return to video game culture as a theme—its narrative focusing on the shenanigans of a group of game testers and programmers grappling with middle age and their own juvenility—the 1990s and 2000s experienced a far more literal translation of video games into Hollywood cinema. Beginning in 1993 with Annabel Jankel and Rocky Morton's *Super Mario Bros.* and continuing with *Double Dragon* (1994), *Street Fighter* (1994), *Mortal Kombat* (1995), *Lara Croft: Tomb Raider* (2001), *Resident Evil* (2002), *DOOM* (2005), *Silent Hill* (2006), *Max Payne* (2008), *Prince of Persia: The Sands of Time* (2010), *Need for Speed* (2014), and the animated *The Angry Birds Movie* (2016), among numerous others, extremely successful video games have been directly adapted for movie theater screens. Frequently panned by critics but nonetheless achieving popularity with audiences, the direct adaptation of popular video games into Hollywood films predominantly takes the game's narrative world as a basis for melodrama nonexistent in the games themselves while translating the game's core mechanics into scenes of visual spectacle. Some examples include the first-person perspective that popularized the first-person shooter (FPS) genre in the game *DOOM* (1993), the mapping and exploration of an underground laboratory in *Resident Evil* (1996), and the use of player-activated slow-motion during gunfights in *Max Payne* (2001), which became the focus of special effects sequences within the games' film adaptations,

specifically hailing audience members who have actually played the games while being of little relevance to the film's stories. Many of these films, like the video games they are based on, inspired sequels of their own; although *Mortal Kombat: Annihilation* (1997), *Silent Hill: Revelation* (2012), and *Angry Birds 2* (2019) are (as of 2019) the only sequels to their respective original films released theatrically, the enormously successful *Resident Evil* franchise has spawned five sequels and is currently being remade.

Recently, studios adapting films based on video games have sought larger audiences and greater critical acclaim by casting Hollywood superstars and Oscar-winning actors in their movies; examples include *Warcraft* (2016), helmed by celebrated director Duncan Jones; *Assassin's Creed* (2016), starring Michael Fassbender, Marion Cotillard, Charlotte Rampling, Jeremy Irons, and Brendan Gleeson; the *Tomb Raider* remake (2018), starring Alicia Vikander; and *Rampage* (2018), starring Dwayne Johnson.

During the 1990s and 2000s, the science fiction and horror cautionary tale of both video game addiction (evident in *The Bishop of Battle*) and a societal overdependence on computer technology also witnessed frequent reiteration. *The Lawnmower Man* (1992) features a scientist who, while experimenting with virtual reality (VR) software, creates a super-intelligent, malicious digital monster out of an autistic groundskeeper, and *Brainscan* (1994) depicts a teenage voyeur and horror enthusiast enacting murderous fantasies due to a survival horror game that hypnotizes and brainwashes him. Horror films such as *Gamebox 1.0* (2004) and *Stay Alive* (2006), in which players respectively become trapped

inside game worlds or die when the game world and the real world begin to merge, continued this cautionary trend into the 2000s. Higher budget, critically successful films also critiqued the potential entrapment of characters inside expansive virtual worlds, with 1999 alone seeing the release of David Cronenberg's *eXistenZ*, Josef Rusnak's *The Thirteenth Floor*, and the Wachowskis' blockbuster hit *The Matrix*. A decade later, Jonathan Mostow's *Surrogates* (2009) and Mark Neveldine and Brian Taylor's *Gamer* (2009) returned to the subject of entrapment in virtual worlds.

In the 2000s, the visual style of video games also influenced particular sequences in major Hollywood films, with specific scenes in *Crank* (2006), *Fantastic Mr. Fox* (2009), and *Avatar* (2009), replicating 8-bit arcade games, platform jumpers, and FPFs, respectively, through their mise-en-scène. Edgar Wright's *Scott Pilgrim v. the World* (2010) incorporated video game visuals, soundtracks, and references to specific games, such as *The Legend of Zelda* (1986) and *Tony Hawk's Pro Skater* (1999), into a movie that uniquely hybridizes elements of film form, graphic novel artwork, and video game design while depicting a generation well versed in all three media.

Academic research on Hollywood cinema's representation and incorporation of video games focuses on multiple issues present in the filmic adaptation of games and game narratives. Such issues include how films depict game hardware and software interacting with the human body (Keane 2002); how spectacle functions differently in games and film (King 2002); how the relationship between narration and emotional evocation differs depending on the medium (Weise and

Jenkins 2009); contrasts between subjective and first-person perspectives in film and games (Galloway 2006); interrelationships between the computer and entertainment industries (Ruggill 2009); and how the different media inform one another in the age of technological convergence—specifically, how convergence relates to the narrative construction of franchises and world-building designed to inform both game and film properties (Jenkins 2006).

Resident Evil Series

Labels to describe genres are usually created after the fact by theorists or critics to refer to a group of artworks with common features that generate comparable expectations. It is rather rare that one work (or a production team) coins the appellation for a genre it is about to breed. Yet, that is what happened with *Resident Evil* (1996). To generically tag it, as was the tradition in Japan, Capcom used the English expression “survival horror” on the cover of the trial version and the commercial one in 1996. What is more, when the game was restarted from a saved file, a message was typed in three parts during the loading screen: “You have once again entered / the world of survival horror. / Good luck!” As the label was not indicated on the covers in the Western Hemisphere, it is through this loading screen that gamers learned about this “world” and began to talk about it.

Resident Evil belongs to the horror genre. In terms of gameplay, it is a mix of action and adventure. Designer Shinji Mikami wanted to make a game in first-person perspective, but he changed his mind when he played the innovative third-person perspective *Alone in the Dark* (1992) crafted by the French Frédéric Raynal and decided to adapt the model. The similarities between the two games are therefore numerous. Focusing on *Resident Evil*, the gamer can either play Jill Valentine or Chris Redfield, two members of the Special Tactics and Rescue Service (S.T.A.R.S.), and their scenarios are slightly different. The 3-D polygonal characters are trapped in the Spencer Mansion, which is pre-rendered in 2-D. Various items have to be found

and puzzles solved to open doors and to progress to new locations and the way out.

To give a cinematic touch, the game world is shown through predetermined camera angles that exploit, in turn, the off-screen space. Tank controls constrain the movements of the player character and render the encounters with the monsters more stressful. Also, resources, such as ammunition and herbs to heal, are scarce and need to be carefully managed. Even though *Resident Evil* was not groundbreaking upon its release, it had exemplarily perfected the novel effects introduced in *Alone in the Dark*. Nor was it the first zombie game; but even if the living dead were not swarming, they could come about behind every door or around every corner. As reviewers of the time asserted, *Resident Evil* could be compared to a horror film. Capcom wanted to make an adult-orientated game, and it was indeed a genuinely scary gaming experience punctuated with effective startle effects.

Upon its entrance to the Spencer Mansion, built in the forest near Raccoon City, an industrialized American city located in the Midwest, the Alpha Team starts to discover the top secret activities of the Umbrella Corporation, a large international pharmaceutical organization inconspicuously developing virus and Bio-Organic Weapons (B.O.W.). This will only be the tip of the iceberg.

The fight between Good and (Resident) Evil evolved into a best-selling transmedia franchise of more than twenty games (excluding the remastered versions and the remakes), ten films (both computer animated and live action—a series of six chapters), and

Packaging for *Resident Evil 7*. (Petrajz/Dreamstime.com)

comics and manga as well as novelizations. The action takes place in the United States, Europe, and Africa (in *Resident Evil 5* [2009], a white member of security forces coming to an African region to kill Black enemies did stir controversy). It features a cast of recurring characters, both female and male: Jill, Chris Redfield, his sister Claire, Rebecca Chambers, Leon Kennedy, Ada Wong, Barry Burton, and Albert Wesker, a S.T.A.R.S. member working undercover for Umbrella. Although there are obviously villains pulling the strings in the shadows, *Resident Evil* is best known for its fiends. An engineered virus turns workers and other creatures into zombies (which are more and more numerous as the series progresses) and B.O.W., such as the Hunter (a mix of gorilla and lizard), the Licker (a combination of feline and reptile), the Bandersnatch, the Tyrant, and the Nemesis (all deformed

humanoids). Some scientists, such as Alexia Ashford and William Birkin, inject themselves with their infectious organisms and transform into worse monstrosities.

To forge the survival horror genre, the formula of the first *Resident Evil* was cloned, iteratively improved, and changed, starting with Capcom itself. *Resident Evil: Code: Veronica* (2000) integrates real-time 3-D environments; the various locations are still seen through predetermined camera angles, but the virtual camera now tracks Claire in the shots, adding an immediate dynamism to the movements. *Resident Evil 4* replaces the fixed camera with one following Leon over the shoulder. When they are hurt, player characters walk with an unsteady gait in *Resident Evil 2* (1998). During parallel event lines, a “zapping” system shows actions taken by one character in one scenario affect

the scenario of the other. As gamers are able to switch partners on the fly in *Resident Evil Zero* (2002), an online multiplayer option was offered in *Resident Evil: Outbreak* (2003), and an off-line co-op mode allows them to play together in *Resident Evil 5*. Up until this fifth installment, to enhance their vulnerability, S.T.A.R.S. members could not run and shoot at the same time. But various evasive and attack moves have been added over time, including new and more accurate weapons (with *Resident Evil 4*'s laser sight handgun standing out most prominently). Through its evolution, the video game series has become more action oriented, leaving out the frightening dimension that was the basis of the initial design.

Yet, and this is one of its strengths, the series is not afraid to experiment and to somehow renew itself. Indeed, notwithstanding that *Resident Evil: Survivor* (2000) used a first-person perspective, *Resident Evil VII: Biohazard* (2017) has been the first full triple-A scary game sold for the PlayStation VR and a notorious return to its roots. That being said, the popular and critical acclaim of the remake of *Resident Evil 2* (2019) also proves that repetition continues to be as important as variation. As a genre that *Resident Evil* has crystallized, survival horror will likely remain in good hands with Capcom's series.

Resolution

The concept of *resolution* is used in computer graphics and is therefore applicable to video game imagery. Resolution refers to the number of discrete units (such as pixels, frames, available colors, or polygons) used to represent (or resolve) a portion of an analog spectrum, in particular, those of space, time, color, or geometry. Because of memory limitations, processing speed, and monitor capabilities, these four types of resolution are always limited in some way, requiring graphic designers and game designers to take them into consideration, to some degree, especially in projects encountering more restrictive limitations regarding resolution.

Spatial resolution is measured in pixels per inch and refers to the amount of detail possible in a digital image. The more spatial resolution that is available in an image, the smaller the detail that can be represented in it (although processing power and software-related restrictions can also limit resolution, as in early home video games, like those of the Atari VCS 2600). The lower an image's spatial resolution, the more apparent the edges of individual pixels will be, resulting in a jagged appearance referred to as *aliasing*. The effects of aliasing can be lessened by using rows of pixels of interpolated colors or tones at boundaries between different colors or tones, to make the transition between

them more gradual; this process is called *anti-aliasing*.

Temporal resolution refers to the number of frames per second used in time-based media. The more frames per second used in moving imagery, the smoother the apparent motion can appear within the imagery. Temporal aliasing, known as *strobing*, occurs because a frame rate is too low to convey a sense of smooth motion, and moving objects appear to jump from one position to another rather than moving smoothly between them. The effects of strobing can be lessened through the use of *motion blurring*, which simulates the blur that an object would have passing through a given span of space in a given span of time, all within a single image. The addition of motion blur to a moving object fills in the gaps between the object's positions from one frame to the next, smoothing the overall appearance of the motion.

Color resolution (or in the case of gray-scale imagery, *tonal resolution*) is measured in bits per pixel and refers to the number of colors available for use in an image or series of images (for n bits there are 2^n possibilities). When the color resolution of an image is low, the jump from one color to another along a gradient is more abrupt and noticeable, resulting in color aliasing or *mach banding*, also known as *posterization*. This can be alleviated through the use of *dithering*, in which pixels of different colors are mixed in changing ratios across the boundary between colored areas, allowing one color to increase while another decreases, simulating a gradient between different colors or tones when the image is viewed from a distance or if the spatial resolution is high enough.

Geometric resolution, when applied to three-dimensional graphics, refers to the number of polygons used to resolve a three-dimensional shape within a three-dimensional space. Low geometric resolution, in which the individual polygons are discernible, results in a blocky or faceted appearance, whereas higher resolution allows for smoother curves and flowing forms. Naturally, simpler objects require fewer polygons, and increasingly complex ones require more. One of the challenges of computer modeling is to represent the object being modeled with as few polygons as possible while still maintaining as realistic an appearance as possible. Low-resolution models can be aided by certain shading techniques, such as Gouraud shading or Phong shading, which apply color or tonal gradients across polygons so that their boundary colors match, making the boundaries between them less noticeable and smoothing their appearance. Other computer graphics processes, such as NURBS, nonuniform rational basis (or Bézier) splines, allow geometric resolution to change dynamically based on the apparent distance from the viewer, to save calculation and rendering time when objects take up less on-screen space (Polevoi 2000).

Different types of resolution can affect and compensate for each other's limitations. For example, the aliasing in an image with low spatial resolution can be eased with higher color resolution that allows anti-aliasing to be done. Higher color resolution also makes motion-blurred imagery possible because blurs require gradients, and smoother gradients, used by shading techniques, can reduce the effects of limited geometric resolution. Higher spatial resolution can

make up for low color resolution by making dithering less noticeable and color gradients appear smoother. The quality of grayscale imagery is also perceived differently from color imagery, with a wider dynamic range of color making up for lower spatial resolution, so a designer wishing to save memory should reduce the tonal resolution in grayscale imagery while leaving the spatial resolution unchanged; in contrast, for color imagery, the spatial resolution of color images should be reduced while the color resolution is left unchanged (Ester 1990).

Even as screen resolutions, memory, and processing speeds increase, the need for economy and continual pushing of boundaries ensures that issues related to resolution will need to be taken into consideration for some time to come.

Resource Management Games

Managing resources is central to many games. In survival games such as *Rust*

(2013) or *This War of Mine* (2014), players must scrounge for medicine, food, building materials, and weapons, while triple-A open-world first-person shooters (FPSs) such as *Fallout 4* (2015) include elements of resource management in the form of inventories and trading systems. In strategy games, such as Paradox Interactive's *Crusader Kings II* (2012) and *Europa Universalis IV* (2013), managing and accruing a variety of "resources," such as political, popularity, cultural, and research points, is the central goal in the game. Resource management can exist as the backbone of gameplay or as an addition to increase immersion and "realism" in the game world.

A resource management game can be understood very literally. For example, farming simulator games demand players plan, cultivate, and harvest their land for agricultural goods, managing agrarian capital and balancing their budget. Various tycoon games, such as *The Rise of Industry* (2018), act as market simulators, where one controls and tries to steer his or her corporation or business to immense wealth and power. Accumulating and increasing your ability to further accumulate certain resources is the core gameplay in these games, which often act more as capitalist simulators with very little narrative or characterization.

In games such as *Banished* (2014), the *Age of Empires* series, the *Tropico* series, and the previously mentioned Paradox Interactive games, players must gather, produce, or otherwise accumulate food, trading goods, money, political power, and natural resources. These games, as opposed to the farming simulator games, use resource management to further expand a city or nation. Often, one must consider military power and global trade

when gathering resources, and researching technology or national ideas can enter into the equation. Resources also assume a more abstract quality; certain talented advisers or courtiers in *Crusader Kings II*, for example, provide you more political power, which is measured by numerical points. You can spend these points on various actions, such as quelling rebellions or increasing your popularity among a county's nobles. Resources need not merely be goods and services but can act more as conceptual in-game capital to be exploited.

Resource management in games can take the idea of a conceptual resource and interpret it in creative and unique ways. Failbetter Games' *Sunless Seas* (2015) puts the player in Fallen London, a steampunk Lovecraftian world below the earth's surface, where you play as a ship captain exploring the Unterzee—a subterranean ocean. Taking a particularly unique approach to resource management, players must balance and manage traditional resources, such as fuel and supplies; however, they must also control the sanity level of their crew, as the terror of exploring the dark sea can push your sailors to the brink. As an explorer, knowledge that others do not have is also an important form of currency—stories of distant shores and horrific vistas can earn you money, fuel, weapons, and crew members.

Two distinctions emerge from the preceding paragraphs. The first regards the role resource management plays in the overall game. Managing resources is a feature in many games, and a resource management game is one where this feature is the crux of gameplay. The second distinction resides in the nature of these resources. Certain games involve the

managing of traditional resources, while others translate *resource* for more abstract or conceptual currencies.

Resurrection. See Death and Resurrection

Retrogaming

Retrogaming is a hobby of playing older console-based games, computer games, and arcade games. Although there are no universally accepted criteria for inclusion in the *retro* category, the label is typically used in reference to discontinued platforms and software developed for such. According to this convention, a game such as *The Legend of Zelda: Ocarina of Time* for the Nintendo 64 is considered retro (because the system is no longer manufactured or supported), but Windows-bound *Half-Life* is not, regardless of the fact that both titles were released in 1998. By the same token, the category also encompasses new games—including original works as well as remakes and demakes (a demake is an interpretation of how a game *might* have

looked if it had been made with older or newer technology)—created by homebrew communities organized around consoles such as the Atari VCS 2600 or the GCE/Milton Bradley Vectrex. In a broader sense, the term can also be applied to so-called retro throwbacks—releases that bring play mechanics and aesthetics reminiscent of earlier eras of game design to modern platforms (e.g., the 2-D platformer *Cave Story* [2004] or the twin-stick shooter *Geometry Wars: Retro Evolved* [2005]).

The emergence of retrogaming subculture has been attributed to a variety of factors, from general interest in the history of the medium, to nostalgic desire to relive personally meaningful gaming experiences, to growing dissatisfaction with the perceived creative crisis of the modern game industry (especially overreliance on licenses and sequels as risk-avoidance strategy in the face of rising development costs). Although personal motivations vary widely, the movement provides a much-needed counterpoint to the forward-looking mindset and rapid pace of change characterizing gaming culture. Perhaps most crucially, it keeps the medium's past alive, testifying to the continued relevance of technologies, design principles, styles—even entire genres—that, over the years, have undergone dramatic changes or been altogether cast aside. Moreover, because the hobby is typically associated with hardware and software collecting, retrogaming plays an important curatorial function, preserving and protecting aspects of game culture increasingly threatened by obsolescence (as a result of lack of support for discontinued hardware, software, and storage formats), “bit rot”

(irreversible degradation of optical and magnetic media as well as decay of data contained in EPROM chips), malfunctions, and physical destruction (both accidental and, as has been the case with a number of arcade games, intentional; see “Suicide Battery”). A similar role is played by a number of community-driven emulation, documentation, and preservation initiatives—most notably the Multiple Arcade Machine Emulator (MAME) and its derivative, the Multi Emulator Super System (MESS). This is especially noteworthy given that organized, institutional efforts of this kind are still relatively rare.

Retrogaming's gradual movement from the fringes toward the mainstream has been, unsurprisingly, accompanied by growing commercial interest. The industry has been quick to capitalize on the “retro revival” with remakes and rereleases of older titles for modern systems. Because their small size makes such offerings well suited for digital distribution, in recent years, they have become virtual staples of platforms such as the PlayStation Network, Xbox Live Arcade, and Wii Virtual Console. In addition, some of the more popular vintage titles from such publishers as Namco, SEGA, and Atari have found their way into a number of low-cost, dedicated consoles. The trend contributes significantly to increasing the visibility and accessibility of retrogaming, but, with the likelihood of rerelease directly proportional to a given game's commercial viability, it also prompts questions about potential distortion of the history of the medium. Furthermore, the use of software or hardware emulation in “retro” products raises concerns regarding the authenticity of the resulting play

experience (as games are taken out of their original social and technological context) or even its basic accuracy (due to emulation errors, altered controls, etc.).

Rhetoric

Rhetoric is a field of study that focuses on communication, persuasion, interpretation and truth-finding, and symbolic language and semiotics. While this list is not exhaustive, the general supposition of rhetoric as communicative action underlies many definitions. The field of rhetoric is both an analytical profession (seeing what opportunities exist in certain situations) and an active profession (being a rhetor). The goal of rhetorical analysis is to understand the means of transformation in changing a person's thoughts, worldview, material realities, or relationships.

Rhetorical criticism within the field of rhetoric specifically refers to applying rhetorical frameworks or methods (often yet not exclusively qualitative) to uncover

meaning, relationships between creators, audiences, material artifacts, and messages within a specific context (see deWinter 2006 for a synthesis on rhetorical criticism; see Paul 2010 for more on rhetorical methods in game studies). As Eyman (2016) writes in his introduction to *Play/Write: Digital Rhetoric, Writing, Games*, "Digital rhetoric sees agency in the interactions and interrelationships of any of the components of a given ecosystem. This is particularly important for digital game spaces, which feature both users and system agents (including non-player characters, the environments in which the actions take place, and the rules that govern in-game interactions)" (7).

Rhetoric as a method of study, then, lends itself well to game studies: it enables scholars to look to the game as text to see what visual, narrative, procedural, or ideological messages are embedded, offering excellent close readings on representation, purpose-driven narrative analysis, or capitalist critiques. It highlights the discourses around games, from the moral concerns and panics of games and violence (often through fantasy-theme analysis) to the instrumentalist views of games as master persuaders and life changers, such as the gamification work forwarded by McGonigal and Bogost (see *Procedural Rhetoric*). It uses material dialectic analysis frameworks to understand hardware, software, spatial setup, group formation, and individual transformation. It creates frameworks to make sense of emergent forms of communication, and work here has often focused on massively multiplayer online role-playing games (MMORPGs), online communities, and, increasingly, human–artificial intelligence (AI) communication.

In his book *Game Work: Language, Power, and Computer Game Culture* (2004), rhetorician Ken S. McAllister articulates a rhetorical method specific for understanding what he calls “the computer game complex” and “game work”: “The creation and playing of games entail different kinds of work, of course,” he writes, “but they all manufacture values ranging from the economic to the moral. And like any piece of artwork, a ‘game work’ is itself a medium through which these values are articulated and reproduced” (26). The rhetorical method that he posits responds to Kellner’s multiperspectival call to action and is grounded in the dialectical tradition and Brummet’s work on rhetoric in popular culture. Borrowing from Burke’s rhetorical “grammar,” McAllister offers this grammar of game work for a rhetorical analysis method based firmly in his analysis of the computer game complex:

1. Agents: “Every computer game begins with an agent: someone—or some collective—is always behind the management of meaning” (45).
2. Functions: “[The computer game complex] would have little influence on anything if [it] did not embody and enact particular approaches to managing meaning. Agents depend on (both consciously and unconsciously) the various ways that rhetoric works in different circumstances to effect change” (47).
3. Influences: “The five major influences on the computer game complex are the same as those that the complex itself imposes on culture: mass culture forces, mass media forces, psychosociological forces, economic forces, and instructional forces” (50).

4. Manifestation: “The computer game scholar . . . can understand the representational rules as a *manifestation* of the developers’ rhetoric, each rule corresponding to a meaning-making or meaning-managing event” (56). Additionally, “through their rhetoric, computer games require players to practice being the subjects that the developers have invented” (58).
5. Transformative Locals: “The shaping of meaning is necessarily dependent on the locale in which meaning making events are invoked. . . . The three categories of ideology that I described earlier—idiosyncratic (i.e., personal), homologous (i.e., communal), and inclusive (i.e., societal)—are the locals within which transformative experiences take place” (59).

Following this, McAllister offers a series of chapters using this rhetorical grammar, articulated together, to understand complex relationships in and around games, from individuals, creators, players, and communities to businesses, marketing, and economic forces. The strength of this analysis is McAllister’s understanding that not all rhetoric is purposeful; rather, rhetoric works at the level of ideology, of mimetic representation oftentimes without intentionality (as opposed to Aristotelian rhetorical traditions). Yet, this rhetoric, often visible at the intersection of these different grammars, shapes and transforms human activity and relationships and, in many ways, gives rise to many of the anxieties surrounding games in culture.

It is not an accident that many game scholars rely on Aristotelian rhetoric as a theoretical foundation: Aristotle’s

writing are “rediscovered” with the Renaissance and the rise of modernity. Aristotle’s purpose was to observe and name the component parts of rhetoric to teach the ruling classes and, in naming those parts, controlling rhetoric and the people affected. In this way, rhetoric seems to embrace games (rule systems of manipulation and control) and deny play. Yet, here too, rhetoric has embraced play, understanding the transformative power of play. In an older piece, Beamlin (1987) notes that play fosters identification—one of the strongest of the rhetorical appeals—and thus play is a strong transformative force. Derrida and Bhabha have also noted play’s rhetorical power in disrupting or subverting power structures. And Wark’s *Gamer Theory* (2007) notes moments of empowerment within the game world through subversive play, such as trolling and trifling. Rhetoric in game studies, then, is not just about persuasion or manipulation; it is about agency, power, and transformation, and rhetorical applications of analysis must account for play as much as it accounts for rules, narratives, visual representations, or even designer and player activities.

Rhythm and Dance Games

Rhythm and dance games are video games that fall under the category of what could be termed the *rhythm-action genre* (Collins 2008). Gameplay is primarily focused on players repeating or coordinating rhythmic audiovisual cues in unison with the game, using either traditional console controls or additional peripheral devices. Avatars are usually of secondary importance in most rhythm and dance games. With the scrolling of rhythm and dance moves taking center stage, avatars are often relegated to background characters and rarely influence gameplay in any way.

One of the first rhythm-action electronic games is often said to be Atari’s *Touch Me* (arcade version, 1974; handheld version, 1978; Collins 2008); however, it was Milton Bradley’s *Simon* (1977), invented by Ralph Baer, that first saw broad commercial success. Gameplay is centered around a circular electronic device with four colored buttons (red, green, blue, yellow), each with its own harmonic tone. Players observed the

audiovisual pattern displayed on the device and then attempted to repeat the pattern correctly by pushing on the appropriate button, matching color, and tone. The patterns became increasingly difficult with each turn. Although seemingly rudimentary compared with current rhythm-action video games, the basic premise remains constant in today's rhythm and dance games.

In 1988, Nintendo released the Power Pad floor mat to accompany the Nintendo Entertainment System (NES) console to be used with games such as Bandai's *Dance Aerobics* (1989) and Nintendo's *Short Order/Eggsploade* (1989). Containing more sensor spots in its dance mat than Konami's *Dance Dance Revolution* (1998), the Power Pad can be seen as an important early technical precursor to incorporating full-body movement in video game play. Another early predecessor to contemporary rhythm-action games, NanaOn-Sha's *PaRappa the Rapper* (1996), uses a similar observation/repetition gameplay technique as *Simon* but also requires the player to successfully match the timing of the repetitions.

The shift to peripheral-led music gaming is attributed to Konami's Games & Music division (later renamed the Bemani Division), with *Beatmania* (1997), a DJ-style video arcade game, later ported to home consoles in Japan and North America, which led a series of thirty-four games released between 1998 and 2007. *Beatmania* can be said to be a direct predecessor to Activision's *DJ Hero* (2009). Konami's *GuitarFreaks* (1998) soared in popularity with the release of fourteen games over the period 1998 to 2006 (Wolf 2007). However, it is Konami's *Dance Dance Revolution*, with

sixteen versions of the game released over the period 1998–2006, that is often cited as being largely responsible for the increasing popularity of rhythm-action games globally (Edge 2010). There are several variations on rhythm and dance gameplay mechanics, such as a memory “observe and repeat” format, in which players watch a sequence and then perform it from memory; testing of coordination skills with scrolling images, such as arrows or music notes that the player has to push with the corresponding buttons on the controller in unison with the images on the screen; and freeform gameplay, in which players are free to create music or dance moves without any gameplay restrictions. Most rhythm and dance games base progression solely on the successful completion of songs that increase in difficulty level as the player progresses. However, there are a few exceptions, such as *PaRappa the Rapper*, which is essentially a narrative-based video game with rhythm-action elements within it.

Although rhythm and dance games can often be played with a standard controller for console versions, most games require specialized peripheral controllers, such as a range of musical instruments for games such as Harmonix's *Rock Band* (2007), Red Octane's *Guitar Hero* (2005), and Nintendo's *Donkey Konga* (2003); dance mats for games such as *Dance Dance Revolution* and Code-master's *Dance Factory* (2006); and headsets and microphones for karaoke-style games such as Konami's *Karaoke Revolution* (2003) and London Studios/Sony's *SingStar* (2004). These peripherals plug into the console and can often fully replace the traditional controller for interface navigation and gameplay.

Although video game interfaces vary depending on the title, many games show a variation of the peripheral controller on the screen. For example, *Guitar Hero*'s interface shows the image of a guitar neck with frets displaying the scrolling notes and chords players must match in sync with the game. Notes and chords are color-coded to match the console's standard controller (green, red, yellow, blue, and orange). Although the video game chords often reference chords on an actual guitar, they are often simplified for the sake of gameplay and therefore cannot be considered a guitar simulation game in the true sense. This is similar to *Dance Dance Revolution*, where the rhythmic sequences of steps are not directly correlated to actual dance moves.

Through technological development, video game controllers have shifted from game-specific devices such as *Simon* to peripheral-centric games such as *Rock Band* and *Dance Dance Revolution* that can be played on multiple consoles. With the development of motion-capture technology such as Sony's *EyeToy* (2003), a peripheral console attachment for the PlayStation 2, and Microsoft Xbox's Kinect, which included a digital camera and motion sensor, video games can be controlled by the player's body movement alone. Games such as *EyeToy: Groove* (2004) and Kinect's *Dance Central* (Harmonix, 2010) encouraged players to move their entire bodies while standing in front of their televisions; their bodies then appeared on the screen, and they attempted to hit targets that were positioned on the edge of the screen according to the rhythm of the music playing.

Other variations of gestural interfaces include Nintendo's *WiiMusic* (2008), in

which players use the Wii Remote and Nunchuk to control a band on the screen (playing a possible sixty-six instruments, including both traditional and nontraditional ones), and Ubisoft's *Just Dance* (2011), which is played while holding the Wiimote. With the increase in commercial success and access to virtual reality (VR) technologies, games such as Harmonix's *Rock Band VR* (2016) offer the player a fully immersive experience. Regardless of the technology driving the experience, rhythm and dance games focus on the player's body as a core element of gameplay.

Ritual

Games and rituals are both millennia-old human activities infused with human meaning-making, and because many rituals have historically taken place in religious contexts, rituals and games manifest a surprisingly deep kinship. Some ancient games, such as the Mesopotamian divination game *Ur*, were both religious and playful. Indeed, the function of these activities so overlaps that the difference between them is perhaps more a matter of perspective than of form or function. Because rituals and games are both contested terms that exhibit immense diversity of practice, all comparative observations must be generalizations. But even the most obvious comparisons reveal that both video games and ritual may be doing some similar things for the people who use them, performing what David Chidester (2005) calls “religious work” whether or not they are explicitly labeled as “religious.” As Ronald Grimes observes, “meaningful ritual-and-media discussion becomes possible when the two domains are neither equated nor segregated but rather differentiated and conceived as sharing a common boundary” (Grimes 2006, 229).

Both rituals and video games are often concerned with storytelling. Scholars have long noticed the close relationship between myth and ritual in religious contexts, as when sacred stories are recited in a ritual context or when rituals are themselves dramatic reenactments of

these stories. In such cases, there is a deep connection between the story and its ritual performance, such that the story can best be appreciated *only* in its ritually performed context. Similarly, video games are often infused with a deeply complex mythology that is revealed and enacted via the player’s performance of it. Most players would be less than satisfied with mere walk-throughs or descriptions of a game’s mythology. They want to perform the story, to enact it.

Rituals and video games are deeply *interactive*. Despite the contested nature of the concept of interactivity, few would deny that both games and rituals draw people in and create a feedback loop of experience. Rituals and games both depend on people *doing* them for them to be meaningful. Rituals are often driven by liturgy, or scripts, of how the ritual is to unfold. Similarly, many video games are scripted via the programming and writing behind the scenes. Both, however, require human interaction and performance for meaning to arise and for the “script” to become something more than the potential for experience. And both, one could argue, shape the performer through his or her movement through the scripted experience. Thus, both video games and rituals are “emergent” in the sense that meaning arises via play or performance and depends on the inputted actions of the player-performer.

This idea of *performance* is an important one for game players and ritual theorists and is of course deeply tied in with storytelling and interactivity. For some ritual theorists, the term *ritual* is replaced by the term *performance* or *ritualization* as a means of emphasizing the interactivity—

the configuration or procedurality—involved in a ritual. As ritual theorist Roy Rappaport notes, “Performance as well as formality is necessary for ritual” (Rappaport 1996). That is, *doing* as well as *scripting* is required. For many ritual theorists, it is not a ritual if it is not being performed. Video game players and designers could similarly argue that it is not a game until someone is playing it. This comparison raises the question of what we should call a video game when it is not being played or while it is in development. Is it still a game? Or is it merely a script, liturgy, or potential performance?

Some scholars of ritual are concerned with whether rituals convey a message to people, either to the performers or to those watching the ritual. This concern echoes similar questions in video game theory about whether games *teach* us how to view the world or what to do in it, or whether they teach us anything at all. The arena of ritual, interestingly, is often viewed as imbued with deep meaning with consequences beyond the ritual itself—even if the impact is simply the maintenance of societal status quo. Rituals are believed by many, scholars and ordinary folk alike, to *tell* us something about how the world works, to help us learn foundational stories, or to reaffirm some sense of cosmic structure and order. The arena of gameplay, however, is often seen by players as having little to no meaningful effect on life beyond the game, apart from perhaps some sense of cathartic purging of emotions or an appreciation for camaraderie achieved in multiplayer games. Yet, both rituals and video games are performative; they invite our investment in a sort of what-if scenario that shapes our investment in a given worldview, and

both invite us to *do* things. It seems hard to deny that both rituals and video games, then, have some effect on how we see ourselves and the world. So do games and rituals communicate anything to player-performers or observers? This argument is far from settled, but the comparison of rituals and games invites new consideration of how such messages may be delivered through performance and through play.

Both rituals and games are defined by rules, or structures, that regulate and limit performance, shaping the player-performer’s experience. Ritual theorist Stanley Tambiah (1985) points out the formalized structure of many ritual experiences, describing rituals as “constituted of patterned and ordered sequences of words and acts, often expressed in multiple media” (128), with content that is arranged with differing degrees of formality, stereotyping or fixedness, fusion of disparate elements, and repetition (Tambiah 1985). In this sense, rules are the structure-providing mechanisms that shape experience. Ritual theorists typically do not use terms like *rules* to apply to the ritual performance, preferring rather to think about *formality* and *repetition*, but in a performative sense, both games and rituals indeed set limits on what we can do and what we cannot to give shape and structure to the emerging experience. Both also draw on previous stereotypes or genre specifications, creating expectations and familiarity in performer-players, who know what to do in new manifestations of the game or ritual because they have seen this kind of thing before. Rules tell us how to see things by telling us what is and is not possible. If there is anything to the claim that both rituals and video games can

shape our view of the world, then looking at what the rules are in any ritual or gaming experience could tell us something about what we are meant to derive from the experience. This, in turn, should enable us to be critically aware participants in *any* rule-based environment.

Some important things are gained by a comparison of rituals with video games. Both experiences are concerned with storytelling and are interactive, performative, communicative (perhaps), and defined by rules. This means that both can also be viewed as mere forms of play or as serious shapers of our worldviews. We can also note that although it may seem to some that religion is on the decline, human beings are notoriously creative, imaginative creatures and will find ways to craft meaningful experiences whether or not we feel comfortable labeling them “religious.”

Riven

Cyan’s game *Riven: The Sequel to Myst* (1997) surpassed its predecessor, *Myst* (1993), in size and scale, containing more than four thousand screens of graphics on five CD-ROMs. It was the best-selling game of 1997 but did not pass *Myst*. *Riven* is notable for the beauty of its design, the integration of puzzles into its world and storyline, and the mood and atmosphere of its various locations, all of which demonstrated that video games could be art.

Riven continues the story of *Myst* and begins with Atrus sending the player to Riven, where his father, Gehn, has imprisoned Atrus’s wife, Catherine. Gehn is himself imprisoned on Riven, although he can travel to the smaller worlds, or Ages, for which he has written descriptive books and linking books. *Riven* is itself one of Gehn’s worlds, and its design reflects his personality and ambitions. Atrus gives the player a linking book, which is really a one-man prison that can be used to capture Gehn. Thus, unlike *Myst*, the player begins the game with two objectives: capture Gehn and free Catherine. Once the player arrives on Riven, however, the prison book is stolen by one of Gehn’s guards and then stolen again by a member of the Black Moeity, a rebel group fighting against Gehn that is

The huts of the villagers on Jungle Island in *Riven* (Cyan Worlds, 1997). (Courtesy of Mark J. P. Wolf)

composed of the indigenous Rivenese villagers. This gives the player a third objective that must be completed before the other two can be—the retrieval of the prison book.

Much of *Riven*'s gameplay involves exploring the five islands that make up Riven and learning their geography as well as learning to operate the machinery and gain entry into various buildings and locations. Many small details are significant as clues in *Riven*, and scenery is often staged in depth, allowing a distant view of places and things that tantalize the player into finding a way to get to them. As in *Myst*, important clues can be found in such things as characters' journals, geographic layouts, maps, and other devices, and deciphering several connected layers of clues is sometimes

necessary to solve puzzles. Along the way, the player learns more about Gehn, who becomes more than simply *Riven*'s villain, and there is also a visit to Tay, the rebels' own Age, and the 233rd Age, where Gehn has his office and bedroom.

The smooth integration and diegetic motivation for *Riven*'s puzzles, the care given to the design and rendering of all its details, the engaging storyline that slowly reveals character and backstory, and the attention paid to lighting, sound, composition, music, mood, and atmosphere all position *Riven* at the pinnacle of contemplative single-player adventure games and result in an artistic work that has yet to be surpassed. *Riven* was followed by three more *Myst* games, *Myst III: Exile* (2001), *Myst IV: Revelation* (2004), and *Myst V: End of Ages* (2005),

as well as the multiplayer *Uru: Ages beyond Myst* (2003).

Rockstar Games

Rockstar Games is a video game publishing label and developer that is best known for its *Grand Theft Auto* games. Formed in December 1998 as a subsidiary of Take-Two Interactive Software, Rockstar is headquartered in New York City but also has development studios in Canada, India, the United Kingdom, and elsewhere in the United States.

Rockstar Games was conceived by the company's president, Sam Houser, as "an elite gaming brand," similar in attitude to the record label Def Jam. The label was also envisaged as a home for games that draw on inspiration from contemporary popular culture and openly shun the cartoon, science fiction, and fantasy themes often associated with video games. To underline this image, the company's marketing often focused on courting mainstream media attention and stoking controversy.

In addition to the best-selling *Grand Theft Auto* series, games published by Rockstar include *Thrasher Presents Skate and Destroy* (1999), *Midnight Club: Street Racing* (2000), *Smuggler's Run* (2000), *Max Payne* (2001), *State of Emergency* (2002), *Manhunt* (2003), *Red Dead Revolver* (2004), *The Warriors* (2005),

Rockstar Presents Table Tennis (2006), *Bully* (2006), *Red Dead Redemption* (2010), *L.A. Noire* (2011), *Max Payne 3* (2012), and *Red Dead Redemption 2* (2018).

Initially, the company existed only as a publishing label, but in its first twelve months, it acquired DMA Design, the UK studio behind *Grand Theft Auto*, and took charge of Take-Two's studio in Oakville, Ontario, Canada, and renamed it Rockstar Canada. Edinburgh-based DMA Design was renamed Rockstar North in May 2002 following the success of *Grand Theft Auto III* (2001). That same year, British developer Tarantula Studios was moved into Rockstar by Take-Two and became Rockstar Lincoln. Rockstar also bought Barking Dog Studios, which became Rockstar Vancouver, and Angel Studios, which became Rockstar San Diego. The company continued expanding its development capacity over the next few years with the addition of Rockstar Vienna (2003), Rockstar Leeds (2004), and Rockstar London (2005).

On June 9, 2005, Patrick Wildenborg released the unauthorized "Hot Coffee" mod for the Windows version of *Grand Theft Auto: San Andreas* (2004). The mod gave players access to an otherwise inaccessible sex minigame that the company had abandoned work on prior to the game's release. Rockstar never intended for the minigame to be accessible to players, and its discovery sparked a high-profile political backlash in the United States that resulted in major retailers removing the game from their shelves, class action lawsuits, and the game's age rating to be increased from Mature to Adults Only. In response, Rockstar recalled the game, removed the offending code, and then reintroduced the game so

Rockstar North headquarters building, in Edinburgh, United Kingdom. (Serge Cornu/Dreamstime.com)

that it could revert to its original Mature rating and regain acceptance from retailers.

The Hot Coffee controversy also prompted the passing of a law in California prohibiting the sale of video games with violent and sexually explicit content to minors (under eighteen years of age). The Entertainment Software Association challenged the law, which eventually led to a U.S. Supreme Court ruling confirming that the U.S. Constitution's free speech rights apply to video games.

As the industry changes, new branches of the company have opened and closed. In 2006, the company shut down Rockstar Vienna. In 2008, Rockstar acquired Mad Doc Software of Andover, Massachusetts, and renamed it Rockstar New England. In 2012, Rockstar Vancouver was closed. In 2016, the company established Rockstar India in Bangalore.

The label's formula continues to prove successful as illustrated by *Red Dead Redemption 2* achieving sales of more than \$750 million in just three days. A feat Rockstar says is the second-biggest opening weekend of any entertainment product, after its own *Grand Theft Auto V* (2013), which made over \$1 billion in its first three days of release.

Rohrer, Jason (1977–)

Active in game design since the early 2000s, Jason Rohrer is best known for the game *Passage* (2007), his third game as a solo developer, and for the role that it has played in the evolving cultural discourse about video games as art. Including *Passage*, Rohrer has developed over ten games that, often through deceptively simple gameplay, imagery, and sound, explore the expressive capacities of the medium of the video game.

Passage is displayed in an unusual 25:4 aspect ratio (100-by-16 pixels), which creates the impression of a narrow horizontal corridor. Players control an avatar, modeled on Rohrer himself, who walks through the game's world, exploring spaces, encountering obstacles, and opening treasure chests. Over a playtime of five minutes, the character gradually ages and, finally, dies. Early on, players have the option of taking on a companion, identified in the game's sprite set as "spouse," who will accompany them on their explorations. Near the end of the game, the spouse predeceases the player character, who then goes on alone. All of this is represented through pixelated graphics—the characters are eight pixels tall, half the height of the overall image—and rudimentary animations accompanied by a plaintive synthesizer tune featuring a vaguely martial snare beat.

When *Passage* was released in 2007, a debate about the artistic legitimacy of

video games had been simmering for some time. *Passage* got a boost in visibility when, in a presentation at the 2008 Game Developers Conference, Ubisoft's *Far Cry 2* (2007) creative director, Clint Hocking, declared *Passage* a "game that made me cry." While there is much more to the game than its lachrymose qualities, many players have indeed been moved to tears—and to new understandings of the expressive potential of video games—by *Passage*.

Rohrer is known for having practiced an asceticism that he calls "voluntary simplicity" in his own life. His games can be pointedly simple, but they are not exactly ascetic. Rather, throughout his career, Rohrer has exhibited an impetus in his creative output to reach for new modes of expression through experimentation with game form. Some of the games favor allegory; *Gravitation* (2008) uses a variable aspect ratio and changes in character ability to express mania, while *Inside a Star-Filled Sky* (2011) imagines the infinite through a shoot 'em up game with a recursive, nested level structure. Some recent games are more literal in their representations of the situations they depict. *The Castle Doctrine* (2014) is a multiplayer game in which players alternately fortify their own homes against burglars and set out to rob the houses of other players, and in *Diamond Trust of London* (2012), players participate in the deceptive practices of the international diamond trade.

Rohrer's games have played a crucial role in the cultural legitimation of video games as an art form, and his work has accordingly been exhibited in culturally validated venues previously inaccessible to game designers, most notably in the acquisition of *Passage* for the permanent

collection of the Museum of Modern Art (MoMA).

Role-Playing Games (RPGs)

Role-playing games (RPGs) have a complex history rooted in fantasy literature, interactive storytelling, and miniature wargames. The first RPGs were of the tabletop (also known as pen-and-paper) variety, meaning that they are typically played together by a small team, headed by a game master. *Dungeons & Dragons* (D&D), developed by Gary Gygax and Dave Arneson in 1974, was the first

commercial RPG and a major influence on the development of the genre. In RPGs, players each adopt the roles and control the actions of their own fictional characters (player characters [PCs]) living in a fictional game world, and the game master describes the world and the actions of non-player characters (NPCs). Much of the conflict resolution, such as battle events or tests of skill, is conducted according to a set of rules and a random element, arbitrated by the use of many-sided dice. Character sheets, rulebooks, and other materials may be used to facilitate play, and there are many individual styles of role-playing, some of them more free form and others more rules oriented. There also exists a version of RPG known as live-action role-playing (LARP), which may involve acting in character, wearing period costumes, and staging the location like a theater production, with fantasy- or science fiction–style props and special effects.

Computer role-playing games were partially derived from tabletop RPGs, although there were also other influences and close ties to the development of such game genres as text adventures and computer strategy games. It is somewhat debatable what makes a "genuine" computer RPG; one feature that is commonly considered a defining one is that all RPGs have PCs with quantifiable features (digital equivalents of the character sheets used in tabletop-style RPGs), and character progression is used as a central measurement of success. Traditional RPG rule systems often include *experience levels*, meaning that successful advancement in the game translates into *experience points* through which a PC can *level up* to new powers and skills. Other skill and training

Akalabeth (Richard Garriott, 1979) [top] and *World of Warcraft* (Blizzard, 2004) [bottom]. (Courtesy of Mark J. P. Wolf)

systems may be used, but the focus on improving one's PC nevertheless remains one of the typical features of computer and console RPGs. Regardless of formal similarities, a single-player digital RPG is a very different experience from that provided by traditional tabletop RPGs. The element of “playing a role” or acting in character is largely lost; instead, various puzzles or quest structures (tasks assigned to a player character) are used to guide the player through plot-driven gameplay.

Some of the most popular computer RPG series include the *Ultima* series (begun with *Akalabeth*, 1979), the *Wizardry* series (1981–2001), and the *Might and Magic* series (1986–2002). These were preceded in the 1970s by early dungeon crawl games that were often created for university computer systems, such as *dnd* (developed by Gary Whisenhunt and

Ray Wood, 1974–75) for PLATO at the University of Illinois and *Rogue* (1980). Often reliant on text, these games were implemented as a digital translation of the core elements in *Dungeons & Dragons* gameplay: a player creates an adventuring character and then proceeds to explore some caves filled with monsters and treasure.

Computer RPGs became increasingly complex during the 1980s and 1990s, with expanding game worlds and improving graphical and sonic features. These increasingly complex computer RPGs provided players with richer interaction options by handing them an entire team of adventurers to control rather than a single player character. Video games spun off on their own evolutionary track in the early 1980s with the release of console RPGs, such as *Dragonstomper* (1982) for the Atari VCS 2600 and *Dragon Quest* (1986) for the Nintendo Entertainment System (NES), with gameplay based on models set by the early *Ultima* and *Wizardry* games, combining turn-based battles with a heavy emphasis on narrative and character development. There exist today several national or cultural varieties of RPG game design, of which the contrast between the linear Japanese RPGs and Western open-ended RPGs is a prominent example.

Multiplayer computer RPG gameplay was first implemented in early multiplayer dungeon crawls, such as *Avatar* (1977–79) in the PLATO system. The first multiplayer RPG with a persistent virtual world was *MUD* (*Multi-User Dungeon*), created by Roy Trubshaw and Richard Bartle in 1978–80. Combined with a graphical interface, MUDs (multiuser domains/dungeons/dimensions)

A screenshot from the role-playing game *Arcadian Atlas*, which was part of a Kickstarter campaign. (Courtesy of Mark J. P. Wolf)

later evolved to massively multiplayer online role-playing games (MMORPGs), of which *World of Warcraft* (*WoW* [2004]) is the most popular contemporary example. A subgenre of action RPGs has also evolved in which all game events are acted out in real time. For example, in *Diablo* (1996), the debt to early *Rogue*-like dungeon games is clear, the most important shared element being the randomly generated dungeon levels. When adapted into a multiplayer game, this kind of action RPG is also in principle suitable for competitive tournament play; however, the popular esports phenomenon has largely evolved with real-time strategy (RTS) games (such as first-person shooters [FPSs]) rather than with RPGs. Single-player computer RPGs still remain popular, including several game series with richly detailed fictional and narrative worlds, including *Fallout* (1997), *Baldur's Gate* (1998), *Neverwinter Nights* (2002), *Star Wars: Knights of the Old Republic* (2003), *Fable* (2004), *The*

Elder Scrolls V: Skyrim (2011), and *The Witcher 3: Wild Hunt* (2015).

The essence or *true* character of RPGs is frequently debated by fans of the genre. Some emphasize the primacy of role-play; others believe it is the gameplay element. The early D&D adventure scenarios were often designed and played out in a conflict-oriented hack-and-slash style, where the battles were the core element and immersion into the player character was considered secondary. Some players had different priorities, and thus potential for disagreement existed as to the goal and purpose of RPGs. One prominent formulation of these views was developed by the RPG community in an online discussion (in the rec.games.frp.advocacy Usenet news group) and later published by John H. Kim as “The Three-Way Model” (also known as the Threefold Model) (1998). This model distinguishes between three popular styles of role-playing: a *dramatist* is playing the game to produce a satisfying storyline; a

gamist player is focused on overcoming satisfying challenges; and, finally, a *simulationist* is someone who emphasizes the internal consistency of events within the world of the game. This last RPG player category later became known as the *immersionist*, where the emphasis is on the player getting involved with the lives of fictional RPG characters, even feeling the characters' feelings. In comparison, Richard Bartle (1996) has analyzed how the main player types in MUDs form four distinctive categories: *achievers* (who play to master the game), *explorers* (who play to experience the game world), *socializers* (who play to interact with other people), and *killers* (who want to use their powers to humiliate other people).

The designers and producers of computer RPGs can be seen to cater to this diversity of player preferences in various ways. The original *Diablo* (1997) style of action RPGs focuses on battles and equipment and thus best serves players with gamist or achiever priorities in gameplay. Most of the popular computer RPGs, such as *Mass Effect* (2007) and the other popular single-player RPG series previously mentioned, combine action, puzzle, and narrative elements in a manner that makes them appeal to a broad range of different kinds of players. In addition, as genre features have started to mix, RPGs often have the traits found in many kinds of games rather than those of a separate genre of its own. For example, the popular *sandbox* games, such as the *Grand Theft Auto* series, also include evolving player characters, rich interactions with numerous NPCs, and quest (task) structures much in the style of single-player RPGs.

There are some clear overlaps or mutual influences as well when the development of strategy games is considered, with *Warcraft III: Reign of Chaos* (2002) an example of a wargame that includes individual, evolving “hero” characters as well as nonindividualized troop units. Adventure games also continue to have many similarities with RPGs in the story-driven character of gameplay in particular; however, they do not focus on player-created characters to the same degree. It should be noted that the online RPG space has also continued to expand with the introduction of virtual worlds such as *Second Life* (2003) and *Habbo Hotel* (2000; now *Habbo*). Many of these environments do away with gameplay elements entirely, becoming purely graphical chat services.

The combination of gameplay challenges, fictional worlds and characters, and online social interactions with real people provides a rich blend of attractions that help online RPGs remain popular. The MMORPG subgenre also displays continuing popularity, with *WoW* having seven major expansion packs released (with *Battle of Azeroth* released in 2018). In casual games, simplified versions of RPGs have been released and marketed as both social and mobile game versions.

Romania

Although video games have been a popular entertainment medium in developed countries since as early as the late 1970s, in Romania, they began to emerge as an important part of youth culture only after the fall of communism in 1989. After Nicolae Ceaușescu's visit to North Korea in 1971, communism in Romania took a nationalist and isolationist turn, and the already feeble cultural relations with the capitalist world were severed (Boia 2017, 153). As a result, in the 1980s, when video games were gaining momentum in the form of arcade games and home consoles, they were inaccessible to the general public in Romania.

After the fall of communism, video games started to penetrate the

Romanian entertainment market, but they had to adapt to the particularities of an emerging deregulated capitalist system. In the context of a nonexistent middle class and the huge inflation experienced by the Romanian economy in the 1990s (Niculescu 2001, 183), authentic games and gaming platforms were scarce. However, because copyright law was not enforced, the average Romanian could purchase affordable clones of Nintendo Entertainment System (NES) consoles, the most popular being the Terminator 2, and pirated games, which were sold more or less clandestinely on stands in markets and sometimes even in stores. (Because these games were counterfeit copies bought from mostly unauthorized distributors, neither buyers nor sellers were really sure what games they were buying or selling, as the cartridge covers only partially matched the game inside. Usually, the name on the cover pointed to the right game series, but the installment was rarely indicated correctly.) Therefore, while fifth-generation consoles such as the Sony PlayStation and the Nintendo 64 were enjoying much success in developed countries, most gamers were still using third-generation consoles in Romania. Nevertheless, one has to acknowledge that this lag was not necessarily detrimental for the gaming community, as Romanian gamers were now recuperating the decade of gaming history that they had missed.

Toward the end of the 1990s, many Romanians could finally afford personal computers. This paved the way for PC games in Romania, which were also bought from clandestine distributors who owned CD writers and sold cracked and pirated copies of original games. By

the turn of the millennium, the local gaming community had made important steps in synchronizing itself with the global gaming culture, in that gamers in Romania now played the same games as those abroad. However, console games were still unpopular among Romanians who were at odds with buying a gaming platform that could not run pirated copies of games. (Alternatively, one could have his or her console hacked; however, authentic games could not then be run on it, and there was always the danger of hacked consoles not running properly.)

Technological progress, cheaper CD and DVD writers, and the spreading of internet availability across the country (in 2018, the internet connection speed in Romania was ranked as being one of the fastest in the world [Melenciuc 2018]) made games in the 2000s readily accessible to anyone with a PC and a broadband internet connection. The enforcement of copyright law was still weak, and so PC users could illegally download any game they desired. The popularization of emulators also enabled PC users to play games that had only been released for the PlayStation, PlayStation 2, Nintendo GameCube, and other consoles. However, the heyday of video game piracy would not last forever.

After 2004, and especially after Romania joined the European Union in 2007, the country witnessed considerable economic growth as a result of European aid funds, foreign investments (Deacu 2017), and the massive amount of foreign currency that the Romanian diaspora sent home to their relatives. This led to the creation of an urban Romanian middle class that, despite the global economic recession that started in 2009 and

reached its peak in Romania in 2011, has continued to thrive and has afforded authentic gaming products. This growing Romanian middle class enabled the emergence of a legal games market, which, along with the new means used by developers to prevent illegal copies and cracking, has made buying authentic copies of games the norm. (One of the most efficient ways by which developers prevent the use of illegal copies is the requirement of an online login, not only for multiplayer but also single-player mode.)

Romanian gaming culture has changed significantly in the past years, and this can be observed in the social practices surrounding gaming and the attitudes toward video games. Because piracy is no longer the norm, many young middle-class gamers lack the technical skills required to download a pirated version of a video game, find the right crack, and solve all the issues that can crop up when running a pirated copy. On the other hand, in the rural and poorer areas of the country, the social practices related to piracy are more likely to linger on.

Romanians have not only been at the receiving end of the video game industry; they have also been involved in the creation of video games. Important video game companies such as Ubisoft, Electronic Arts (EA), and Gameloft have opened branches in Romania over the past years, with Ubisoft coming to Romania as early as 1992. Some of the important video game series that Romanian studios have helped develop are *Assassin's Creed* and *FIFA*.

Romero, Brenda (1966–)

Brenda Romero is an American game designer and developer. She began her career in the industry as a tester at Sir-Tech Software in 1981, working in a variety of roles on the company’s *Wizardry* series of role-playing games (RPGs) and ultimately designing *Wizardry 8* (2001), which *Computer Gaming World* named RPG of the year. After leaving Sir-Tech, she worked on console adaptations of *Dungeons & Dragons* games at Atari and then on *Playboy: The Mansion* (2005) for Cyberlore Studios. Her research for the game formed the backbone of a book on the subject, *Sex in Video Games* (Charles

River Media, 2008), which considers the history of sex in video games along with ethical concerns and worries about censorship. Afterward, she worked as creative director for Slide and then Lolapps before leaving to join the social media game company Loot Drop, which she cofounded with John Romero in 2010.

Romero has brought her game design expertise to university settings, first serving as chair of the Savannah College of Art and Design Interactive Media and Game Development department and then as designer in residence for the Games and Playable Media Program at the University of California at Santa Cruz. She cofounded independent game company Romero Games with her husband, John Romero, in 2015 and is currently program director of the MSc program in Game Design and Game Development at the University of Limerick. With Ian Schreiber, she is the coauthor of two books, *Challenges for Game Designers: Non-Digital Exercises for Video Game Designers* (Charles River Media, 2008) and *Breaking into the Game Industry: Advice for a Successful Career from Those Who Have Done It* (Cengage Learning, 2011).

In addition to her work in digital games, Romero has received critical acclaim for her tabletop game designs, many of which are under the series umbrella of “The Mechanic is the Message,” a reference to media theorist Marshall McLuhan. These games raise serious questions about morality, history, and social issues. Romero designed the first of these games, *The New World* (2008), to explain the horrors of the slave trade, and in particular the Middle Passage, to her daughter. *Train* (2009) is a board game about the Holocaust that

considers players' complicity in systems. It has been exhibited internationally, covered extensively in the press, and was recognized with the 2009 Indiecade Vanguard Award. The other completed game in the series is *Siochân Leat* (2009), which traces Romero's family history, beginning with the Cromwellian war in Ireland. Several other games are in development, including *Mexican Kitchen Workers*, which exists as a prototype.

In 2006, *Next Generation* named Romero one of the 100 Most Influential Women in the Game Industry, and in 2008, *Gamasutra* listed her in its Top 20 Women in Games. She has also been recognized with the Game Developers Choice Awards Lifetime Achievement Award in 2013, the Game Developers Ambassador Award in 2015, Develop: Brighton's Development Legend Award, and a British Academy of Film and Television Arts Special Award in 2017. In 2018, *PC Magazine* listed her as one of the 10 Most Influential Women in Game Development.

Ross, Bonnie

Bonnie Ross is an American game developer who has worked as a producer, executive producer, and general studio manager before founding and assuming the role of corporate vice president of 343 Industries. Ross graduated from Colorado State University, where she majored in technical communication with minors in physics and computer science. In 1994, she began working at Microsoft in production in their newly created PC sports gaming division, which led to her first game release, *NBA Full Court Press* (1996). During her time in the Microsoft Game Studios, Ross codeveloped or published a slew of successful titles, including *Counter-Strike* (1999) for Xbox, *Jade Empire* (2005), *Psychonauts* (2005), *Gears of War* (2006), *Mass Effect* (2007), and *Zoo Tycoon* (2001), among others.

In 2007, Bungie—creators of the *Halo* franchise—parted ways with Microsoft to create new games, and Ross responded by creating 343 Industries, a subsidiary company that oversees the entirety of Microsoft's highly successful *Halo* game franchise. Already a fan of the *Halo* franchise, Ross saw the strength in the title in the narrative tie-ins and character development as well as the large open world that needed further exploration. She has brought to market a number of well-loved titles in the universe: *Halo 3: ODST* (2009), *Halo: Reach* (2010), *Halo: Combat Evolved Anniversary* (2011), *Halo 4* (2012),

Halo: Spartan Assault (2013), *Halo: The Master Chief Collection* (2014), *Halo: Spartan Strike* (2015), *Halo 5: Guardians* (2015), *Halo Wars 2* (2017), *Halo: Fireteam Raven* (2018), and *Halo Infinite* (2020). In addition to the games, Ross oversees a transmedia approach to the brand, helping to create the *Halo* television series for Showtime and maintaining the book tie-ins, many of which have been named *New York Times* Best Sellers. She credits the strength of the fan community with the transition and strengthening of the brand.

In 2014, Ross was promoted to the title of corporate vice president at Microsoft, remaining in leadership of 343. During her time at Microsoft, she cofounded the Microsoft Women in Gaming community to facilitate networking and mentoring for women in the industry. She also speaks at middle schools and high schools to encourage girls and young women to see games as a creative practice and the technologies associated with creation as intimately involved with expression and creativity rather than an alienating technology. She has further instituted a lifetime ban on Xbox Live to those who make discriminatory comments, arguing that game developers have a personal responsibility to create an inclusive and respectful community.

Ross was included in *Fortune* magazine's 10 Powerful Women in Video Games in 2014 and was inducted into the Academy of Interactive Arts and Sciences Hall of Fame in 2019.

RPGs. See Role-Playing Games

Rules

Linguistically, the word *rule* has three meanings in relation to play: that of a guideline, standard, or regulation (mostly directive of actions); that of a rational regularity (mostly directive of thought); and that of a predictable, periodic recurrence of phenomena (mostly directive of perception). Rules of video games fall into the first category and are therefore close to regulations and standards for social behavior, such as traffic rules or etiquette. Rules of a game can be seen as a set of recurring instructions, the validity of which appears to be set but that can be terminated, changed, or overruled at any time, as long as these changes occur by mutual consent of all participants. However, at the same time, the rules of a game are interwoven with the general idea of *gaming*. Depending on the general conceptualization and definition of *game*, the significance and evaluation of rules change.

In German idealism (such as Schiller or Kant), free play (without rules) is perceived as emancipatory because people are able to interact playfully with the world through trial actions without fear of consequences. The absence of rules during free play, and the self-referentiality of the game, amount to its significance. This concept of the ideal and liberating game is opposed to the functional idea of

the game. This concept of game questions the idea of trial action without consequences (Bateson 2000; Dewey 1916). This aspect of the interrelation between games and rules has especially inspired Juul's work *Half-Real* (Juul 2005). Juul argues for an ambivalent status of the video game between "real" and "fictional," whereas the "real" is represented more or less through the system of rules. However, the variable functionality of rules is guaranteed by the fictional projections of video games. Juul's concept points to an important difference, which can be condensed by the term "magic circle."

The magic circle points back to Johan Huizinga's theory of games. For Huizinga, the magic circle describes the border within which a game is played as well as what is outside the context. This characterizes our current understanding of rules. His anthropological theory of "homo ludens" sees the game as a voluntary activity within certain boundaries of space and time following voluntarily accepted yet binding rules. Although his emphasis on the observation of rules in his definition of *game* was criticized, it has subsequently gained recognition as an important criterion for the definition of *game*. Rules not only confine competitive games in space and time but also determine the course and character of the game. Rules constitute the requirements for winning and the space of action. They limit the actions of the playing subjects, and they are set, fixed, and can be reproduced. Nevertheless, the supposedly mandatory necessity of rules is often in conflict with the element of contingency in games; the true cultural and philosophical value of games may lie in this dichotomy.

However, this strict separation leads to a problem because it upholds the difference between real and fictional (as mentioned by Juul); the rule seems to be part of both worlds. Rules are, on the one hand, part of the "real world," and, on the other hand, they help build the fictional worlds of video games. While playing a video game, we tend to recognize the obvious, constitutive rules. The invisible rules (e.g., "You have to do something or you will lose") are operative but exist outside the formal contours of the gaming technology. It is only by critically examining multiple layers of rules that one can understand how regimes of rules—as expanded systems of internal and external regulations—play with gamers just as they play with games.

Philosopher John R. Searle's classification of rules differentiates between *constitutive* and *regulative* rules. Constitutive rules are those that enable actions. In the case of the rules of video games, it at first appears that this type of rule is the most important. Without these rules, the game and its competition could not exist: if the ball hits the goal, you get a point. Constitutive rules are therefore negotiated, based on agreement, and overt in form. Regulative rules, on the other hand, are the sometimes ambiguous and explicit standards and agreements that structure intersubjective societal cooperation. They are closely connected to a society's common sense and for the most part appear to be invisible and naturalized.

One issue in video game debates regarding rules is whether games can be functionally defined based solely on regulative rules. Video games are unique because of the technical ability of programs and algorithms to enforce rules

(both constitutive rules and regulative rules) automatically during gameplay. This also makes it appear that the rules of a video game cannot be broken by the player (apart from such things as cheat codes and hacking), especially in single-player games where there is no social contract between players. According to Huizinga, games thrive from the coexistence of obeying constitutive rules and the purposeful breaching of those rules. But the breach of constitutive rules does not lead to the end of the tacit agreement needed for the game; it can be part of the enjoyment of the game. In a way, cheat codes and walkthroughs seem constitutive of the gaming experience. However, breaches of the regulative rules lead to the sport being spoiled, so to speak. A good example may be the strategy of “camping” in multiplayer shooting games such as *Counter-Strike* (1999), a tactic in which a player obtains a strategic position somewhere on the map and waits for other players to arrive to kill them. It is a legitimate style of play but is often discussed in player communities as unsportsmanlike.

It is necessary, then, to at least differentiate between the regulative rules of the game itself that differ from the technological rules of the game. The latter are rules that are inscribed in the instrument itself as part of its workings and therefore do not appear as explicit instructions (such as the way the game engine simulates the laws of physics that are defined by the program code of the game engine). Thus, the rules represent at least a link between the game itself, the software application, and the hardware on which it runs. In video games, it does not seem possible to break the regulative rules and technological rules. Cheat

codes and hacking may sometimes be partially breaking the technological rules, but in most cases of cheating (such as camping, the god mode, or full ammo patches), the possibilities of the cheat are intrinsic parts of the game codes themselves.

Because of the communication between players present in multiplayer games, constitutive rules can also be in effect in video games. In this case, the strict determination of the game’s outcome by regulative rules and technically implicit rules would partially dissolve. The suggestion that the rules of video games leave no room for (intersubjective) negotiation and flexibility leads to the conceptualization of video games as a system of dominant rules. Although it is easy to focus on the regulative rules of video games, the presence of constitutive rules in multiplayer games reveals that the playing of such games involves more than simply the implicit technical rules of the game programming. Such things as game modifications, cheating, machinima, and so forth should be seen as places of negotiation regarding the constitutive rules of video games.

Russia

Soviet arcade games included slot machines and electromechanical arcade games such as *Morskoi Boi* (*Sea Battle*, 1981), *Tankodrom* (1981), *Rally-M* (1981), *Sniper* (1981), and *Safari* (1982). In *Sea Battle*, players shelled enemy ships; *Rally-M* was a racing game; and in *Sniper*, players shelled targets (see <http://www.15kop.ru/en/>). Such coin-operated gaming machines were usually installed in urban parks and cinema lobbies and were very popular among Soviet children and adults. From the late 1970s to the early 1990s, Soviet military factories produced some seventy different arcade games; however, “production of the games ceased with the collapse of communism, and as Nintendo consoles and PCs flooded the former Soviet states, the old arcade games were either destroyed or disappeared into warehouses and basements” (Zaitchik 2007).

In 1984–85, Alexéy Pazhitnov developed the first Russian video game, *Tetris*, which involved tetrominoes that fell and disappeared as players filled each row.

The game soon became very popular not only in Russia but also abroad. *Tetris* was not copyrighted at first, allowing it to spread even faster than it would have otherwise.

In 1989, Nikita Skripkin created (for developer Locis) a very opportunistic computer game for the time, *Perestroika*, with a splash screen of Mikhail Gorbachev against the Kremlin wall. The game used the keyboard’s arrow keys to send a frog “democrat” through the swamp, jumping from lily to lily while trying not to drown or be eaten by other frogs, the “bureaucrats.” Lilies periodically reduced in size, disappearing and reappearing, and the speed increased with each level. At higher levels (“Milestones”), computer-controlled frogs appear, the “bureaucrats” trying to catch the player’s frog “democrat.” The round ends when the lily pad that the frog is sitting on disappears, or the frog jumps into the water, or it “eats” a bureaucrat. The game was a success with consumers.

The rapid development of the video game industry in Russia after 1990 contributed to the massive expansion of the internet in Russia. The early twenty-first century was a turning point for Russia in the intensive development of multiplayer browser video games on social platforms (such as Facebook), including *Mafia* (2006), *Virtual Russia* (2007), and *Soul* (2013), and it was also when Russia began to develop video games for mobile phones. Today, social video games are dominant in Russia; these games are created and distributed by companies such as Mail.ru Group, Crazy Panda, Plarium, and Social Quantum, which control 50 percent of the Russian market for

video games (*Review of the Game Market* 2012, 18).

FOREIGN IMPORTS

By the 1990s, the Russian video game market was one of piracy, with many Western novelty games coming in illegally. In the twenty-first century, a significant percentage of the video game market is still imports (almost all well-known foreign video games, especially hits, can be found in the Russian market), while Russian manufacturers seek to fill the domestic market. In 2012, the Russian video game market reached USD 1.3 billion (almost one and a half times as much as in 2010), exceeding the income received from the Russian cinema box office, which was USD 1.2 billion for 2012. Despite all these achievements, the worldwide market share of video games for Russia is low, at only 2.2 percent (*Game Market in Russia* 2012, 4–6).

The growth in profit of the video game market in Russia is largely dependent on increasing the influence of online games (the market share of the online segment increased in 2012 by 64 percent to USD 900 million). In general, their volume has grown, over the period of 2010–12, to 2.4 times what it was before, while the market for off-line games dropped by about 12 percent (*Game Market in Russia* 2012, 4–6).

Significant increases occurred in the spread of video games in Russian social networks, and by the end of 2012, they reached a monthly audience of 52.6 million people. For example, playing video games occupies about one-third of social networks' daily audience (which is generally 9 million users). And the average social network users who play are willing

to spend about USD 15 per month to pay for their online games (*Games Market in Russia* 2012, 7).

Massively multiplayer online games (MMOGs) are popular in Russia, particularly because they are free-to-play (F2P) games. In 2012, profit from casual games in Russia dropped significantly; however, these games are only 1 percent of the total Russian video game market.

RUSSIAN NATIONAL HISTORY AND VIDEO GAMES

During the 1970s and 1980s, games were too primitive for historical themes to develop. The Communist regimes did not suppress video game production, but before the 1990s, all Soviet video games were primitive. The Soviet regime did not buy Western video games to keep them from competing with domestic game products. The change came after the fall of the Communist regime, when technology allowed more complex plots and themes in games, including historical ones.

Despite the wide range of Russian history, game developers have mainly focused on military issues and battles of World War II (Belyantsev and Gerstein 2010, 282). However, there are exceptions. 1C Company released a military strategy game, *XIII Century: Rusich* (2008), in which the player takes on the role of the prince of Pskov. Chelyabinsk Regional Juvenile Library employees created a video game, *How the Urals Saved the Battle of Borodino* (2012), after the events of the War of 1812. The main characters of this video game, Ural teenagers, go to war in 1812 to fight the French. One of the most popular video games about

Russian history is the strategy game *European Wars: Cossacks XVI–XVIII Centuries* (2001).

Russian school teachers of history have used video games to provide an interactive way to “survive” historical events to encourage secondary students’ interest in history. The best games not only impart knowledge of history, geography, ethnography, and culture but also help students to understand the causes and consequences of certain events and learn about what life was like for people of various ages (Chernov et al. 2009, 46).

Russian strategy-based video games also examine recent history. For example, *The Truth about the Ninth Company* (2010) virtually reconstructs events of the war in Afghanistan in 1988, and *Confrontation: Peace Enforcement* (2008) opportunistically plays on the military events in Georgia and South Ossetia in August 2008, mixing history with fantasy (Rus-sobit 2008). Unfortunately, the extensive use of historical video games reiterates the need for media education, which aims at raising the level of information literacy, media literacy, and media competence of people of all ages.

DOMESTIC VIDEO GAME PRODUCTION

One of the first video game companies in Russia in 1991 was Gamos, created by E. Sotnikov. Gamos released the logic-based video games *7 Colors* (1991) and *Color Lines* (1992) and is best known for *Sobor* (1991), *Sky Cat* (1991), *Columbus Discovery* (1992), *Balda* (1993), *Tank Destroyer* (1993), *Corners* (1993), *Kalah* (1993), *Magnetic Labyrinth* (1993), *Regatta* (1993), *Wild Snake* (1994), *Flip Flop* (1997), *Snake Battle* (1995), *Pilot*

Brothers: On the Trail of the Striped Elephant (1998), and *Pilot Brothers: The Case of the Serial Maniac Sumo* (1998).

Gamos’s main competitor was the Russian company Nikita (renamed Nikita Online in 2007), organized by Nikita Skripkin and Stepan Zotov in 1991. During 1992–97, the company released the educational video games *Wunderkind* (1995), *Happy Birthday* (1995), *Anatomik* (1996), *Journey through Europe* (1996), *Twigger* (1996), *Magic Dream* (1997), and *Parkan* (1997) and the arcade game *Hunter on the Road* (1997), among others. Nikita entered into agreements with Scandinavian countries to get data on the educational games used on three thousand computers at kindergartens and schools. Since 1999, Nikita has produced browser-based minigames and entered the German video game market. In 2002–3, Nikita, along with 1C Company, developed the first Russian multiplayer online game, *Sphere* (2004). In 2006, Nikita released three important projects for the Russian market; the browser-based game *WebRacing*, the economic strategy game *Truckers: Transport Company*, and, together with the television channel TNT, the online simulation game *House 3*, playing on the success of the reality TV show for youth (later, the project was called *Avatarika*). In 2012, Nikita Online relaunched the entertainment portal *GameXP* (www.gamexp.ru) with dozens of online games and social networking games. By 2013, there were ten million Nikita Online users, and the company had developed more than one hundred video games in a variety of genres.

In 1993, the distributor and video game producer Buka Entertainment was

created and has since successfully distributed gaming consoles for SEGA, Nintendo, and Sony and created games that include *Russian Roulette* (1996), the quest *Petka and Vasily Ivanovich Save the Galaxy* (1998), *Education of Neznaika* (1999), *Magic Chest* (1999), and *Magic Game* (2012). Since 2000, the company has developed new video games for children under the name Bukashka and expanded its offerings with *Pacific Storm* (2004), *Metro: Last Light* (2013), and *Adventures of the Hunter* (2010) for the iPhone.

Another well-known Russian company, IT Territory, founded in 2004, publishes MMOGs (e.g., *Legend: Legacy of the Dragons* [2006]) and casual games, and in 2007, it became a part of the holding company Astrum Online Entertainment, along with Nival Online, Time Zero, and Nikita Online. Finally, the company Gameland is the leading publisher of game magazines, including *Land Games* and *PC Games*, and is the owner of the internet portal www.gameland.ru.

Without downplaying the role of the “old” Russian video game companies, it should be recognized that today Russia is dominated by relatively “new” companies for the development and creation of social online video games, such as Mail.ru Group (<http://corp.mail.ru>), Crazy Panda (<http://crazypanda.ru>), Plarium (<http://www.plarium.ru>), and Social Quantum (<http://www.socialquantum.ru>), that control 50 percent of the Russian video game market (*Review of the Game Market in Russia in 2011* 2012, 18). Mail.Ru Group is the most popular Russian free e-mail service, and as the operator of two leading Russian social networks, MoiMir@Mail.Ru and

Classmates, it also owns a significant stake in the social network V Kontakte. Mail.Ru Group is actively engaged in browser-based video games (including games in social networks and mobile devices) and owns the rights to seventy online games in Russia, including the foreign *Perfect World* (2005), *The Lord of the Rings Online* (2007), and *Warface* (2013), and their own developments, such as *Legend: Legacy of the Dragons* (2006), *Allods Online* (2010), and more. Crazy Panda also develops social and mobile games, such as *Zaporozhye* (2011), and its online games have more than fifty million registered users. Among Plarium’s hits are the popular video games *Stormfall: Age of War* (2012), *War of Thrones* (2011), *MarketCity* (2013), and *Poker Shark* (2012).

VIDEO GAME PLAYERS IN RUSSIA

The average age of video game players among the urban population of Russia is thirty-three years (54% of them women and 46% men), 45 percent of them are married, and 58 percent have children (*Game Market in Russia* 2012, 13, 29), which proves that games are interesting to not only teenagers but also to adults. Furthermore, 87 percent of the Russian internet audience play video games more often than once a month, and 50 percent of them play every day. Due to the intense proliferation of tablet computers and smartphones, the number of Russian gamers playing games on these devices has increased to about 40–50 percent of the surveyed internet users. And about 60 percent of Russian internet users play video games online in cities with populations of more than one hundred thousand people. Most Russian

players spend about 30 percent of their leisure time playing video games, both on weekdays and weekends. As much as 75 percent of Russian gamers are paying for video games, approximately 19 percent of their total spending on leisure, which also includes spending on restaurants and cafes (24%), sports (20%), and cinema (16%) (*Game Market in Russia* 2012, 24). According to Anisimova, 78.1 percent of video game players are thirty years old or younger, and 90.3 percent of them are male. Young men prefer games with three-dimensional graphics, role-playing games (RPGs), strategy games, and puzzle games, and young women prefer adventure games and card games (Anisimova 2004, 20). These studies proved that video games have aroused people's aggression, anger, addiction to the scenes of virtual violence, and emotional alienation (Anisimova 2004, 20), and they have become addictive (Lipkov 2008; Piljugin 2010). Similar phenomena were identified by my own study of underage gamers in Taganrog (Fedorov 2005).

There is an increase of interest in the virtual world not only by adults, university students, and grade school children but also by preschool children. In 2007, 80 percent of Russian preschool children said that they have a home computer; by 2008, this figure had increased to 92 percent, and by 2009, it had risen to 98 percent. The percentage who played computer games rose from 58 percent of preschool children in 2007 to 82 percent in 2008 and 94 percent in 2009. An even more rapidly growing number of children play computer games on their own, without the help of adults, from 28 percent in 2007 to 62 percent in 2009. The

most popular games among preschoolers are various video game simulators that allow the player to control cars, planes, and helicopters, and boys are more passionate about these games. Simple puzzle games, arcade games, and games that require caring for virtual animals are played more by girls (Brevnova 2012, 20–21).

A sociological study of the urban population of Russia (with a sample of 2,033) showed that 87 percent of the urban internet audience plays video games more than once a month, and 50 percent play every day (*Game Market in Russia* 2012, 11, 20–21); however, countrywide, these figures are more modest, according to the research company GfK-Rus, who conducted a survey in 2010, in fifty-two regions, territories, and republics of the Russian Federation, with a sample of 2,205 respondents (including small towns and rural population, for whom internet access is often difficult). According to GfK-Rus, the number of Russians who play video games totaled 28.4 million people (i.e., not more than 24% of the adult respondents), 34 percent of which play video games each day, which is 16 percent less than in cities with a population of over one hundred thousand residents. The number of video gamers in rural areas (17.7%) is significantly lower than the urban average in Russia (Davydov and Nemudrova 2011, 110–111).

In general, the share of gamers among Russian men is 32.6 percent (including 12% who are active), and among women these figures are much lower (16.5% and 4.9%, respectively). The sixteen- to nineteen-year-old age group accounts for the peak gaming

activity (62.1% of these, including 30.3% with a very high level of activity). Among Russians aged forty to forty-nine, 15.1 percent are active players in the video games (Davydov and Nemudrova 2011, 111). And though 45 percent of gamers in Russian cities (with a population of more than one hundred) are married (*Game Market in Russia* 2012, 13, 29), in general, only 19 percent of Russian married respondents play video games.

The typical domestic employment of video game players are school or university students (66.6%), employees with higher education (33.1%), or unemployed (31.5%), with the time spent by Russian gamers on video game at 126 minutes, on average (Davydov and Nemudrova 2011, 111). The largest subgroup, 34.2 percent of all Russian players, are so-called conservatives, for whom games are an insignificant part of their lives; their average age is 34.6 years, the majority are women (56.2%), and only 14.5 percent play video games daily. But gamers who are “fans” (9.1% of Russian video game players) are young men with a mean age of 25 years and average playing time of 195 minutes per day. Among Russian players, the most popular genre of games were puzzle games and jigsaw puzzles. They attracted 47.5 percent of respondents, whereas 30.8 percent prefer games like everyone else. Racing games were second most popular (41% of gamers’ preferences), and shooting games were third (27.1%) (Davydov and Nemudrova 2011, 117).

Video games have become increasingly popular in Russia, and by 2013, video game sales exceeded that of film distribution for the first time. With the

development and further expansion of the internet in Russia, we can expect significant increases in the online game market. And the increase in sales of high-definition televisions, smartphones, and tablets will increase sales of mobile games and cross-platform games.

S

Santiago, Kellee (1979–)

Kellee Santiago is a Venezuelan American game designer and producer known for her work in independent games. Her interest is in games as a medium for evoking emotional responses, and she has been a leading figure in art games.

During undergraduate studies at the Tisch School of the Arts, Santiago was active in theatrical productions, where she regularly incorporated interactive digital media. She pursued a master's degree in interactive media from the University of Southern California, initially intending to remain in theater; however, after realizing that the reach of a student project (to which she had contributed) had exceeded the audience at every theatrical production, she became increasingly involved in game production. After graduating in 2006, she cofounded and served as president of Thatgamecompany.

At Thatgamecompany, Santiago contributed to the design and production of the company's early titles, including *fLOW* (2007) and *Flower* (2009). *fLOW* was based on Jenova Chen's master's thesis project on the concept of dynamic difficulty adjustment and the concept of flow states. In *Flower*, which is considered a spiritual successor to *fLOW*, the player is the wind, moving a flower petal through the air. These titles established Thatgamecompany as a leader among independent video game studios and met with critical acclaim. At the 2008 Game

Developers Choice Awards, *fLOW* was nominated for the Innovation and Best Debut awards and won the award for Best Downloadable Game. It received further nominations from the Academy of Interactive Arts & Sciences and the British Academy of Film and Television Arts. The Academy of Interactive Arts & Sciences also recognized *Flower* with multiple awards and named it Casual Game of the Year for 2009. In 2012, the Smithsonian American Art Museum included both *fLOW* and *Flower* in its exhibit, *The Art of Video Games*.

After departing Thatgamecompany in 2012, Santiago took a role at OUYA as head of developer relations and content acquisition for the platform, where she worked until the company's sale and dissolution. Since 2016, she has worked on production and product development roles at Google, focused on the company's augmented reality (AR) and virtual reality (VR) game projects. She is also a founding partner of Indie Fund, an investment fund focused on independent game development projects, which launched in 2010. In 2011, *Fast Company* named her one of the one hundred most influential women in technology.

Saudi Arabia

Saudi players are considered among the most hardcore gamers in the Middle East; in a wealthy country where conservative culture controls most social activities, video games prove to be an affordable retreat for the young generation. The Saudi market is the biggest in the Middle East, with 4.5 million users and nearly USD 242 million in revenue in 2018. Yet, the rise of Saudi developers did not match such a surge in demand. The small number of talented developers could not upgrade their demos into full products, giving local investors a limited view of the capabilities of domestic talents, one that was shortsighted and overwhelmed by the consumption of entertainment products rather than the production of them. However, Semaphore Lab has proven to be an exception. This Saudi game development and animation studio was founded in 2010 by Ahmad Jadallah and released its first game, *Al Rekaz (Unearthed: Trail of Ibn Battuta)*, in 2013, an adventure game with many similarities to Naughty Dog's *Uncharted* series but with local flavor. The company was praised, as it was the first local game supported on most platforms, including consoles, PC, and mobile. In 2016, the company released *Badiya: Desert Survival*, set during World War I, and its portfolio includes many different genres of games with local themes that are soon to be released.

During the rise of mobile games, a local company called Lumba, founded in

2013, introduced localized versions of games by Finnish company Supercell, including *Tribal Rivals* (2014), a direct reskin of *Clash of Clans* (2012), and *Tribal Mania* (2016), a reskin of *Clash Royal* (2016). Both games enjoyed reasonable success locally, with almost 6.5 million downloads of both games.

Save Function

The save function allows players to record their current progress and position in a video game to allow them to return to that point the next time they play. Save functionality did not exist in early arcade video games but became a common feature of video games in domestic spaces on home game consoles and personal computers. Arcade games have historically encouraged a shorter total playing time by requiring the player to insert a coin to initiate a game session and then generally limiting the player to a few opportunities, or "lives," for each such session; in a sense, a player "rents" an arcade game by inserting a coin. This design characteristic maximizes profitability of a given arcade unit

by essentially forcing players to regularly insert more coins to continue play or start a new game. The economics of home console-based games did not require the game maker to encourage shorter playing times; because consoles and their games were sold outright, the length of playing time for a given game was no longer directly linked to its potential revenue. Thus, although arcade games continued to employ the same basic economic model, home games could encourage longer playing times, and save functionality emerged as a means to allow players to continue play from an earlier session to reduce player frustration.

The game dynamic in arcade games of multiple tries, or lives, per play session can be traced to mechanical coin-operated games such as pinball and Japanese pachinko machines. These mechanical precursors to electronic video arcade games gave the player a predetermined number of chances to play the game in exchange for the deposit of a coin, often supplying the player with a few metal balls. Using paddles and other methods of control, the player then manipulated and maneuvered these metal balls one at a time across an enclosed playing board. These games featured areas of the board that rewarded players with differing amounts of points for rolling the ball into particular regions of the board. Other areas removed the ball from the playing board and thus eliminated one of the player's "tries" on the board.

Much like these mechanical precursors, early arcade video games similarly required players to start the game from the beginning each time it was played and only allowed a player a few tries, or lives, per game session. Exidy's *Star Fire* (1979) introduced the high score table,

which rewarded more skilled players by allowing those with the most points to record their initials or name on the game. This effectively encouraged players to challenge the scores of other players and generated more revenue in the process. Although *Star Fire* and subsequent titles allowed players to save high scores on the machine, arcade games have typically not allowed players to save and continue their progress within a game at a later point.

Because arcade game revenue depended on the number of times a game was played, arcade games often accentuated skill and speed and placed little emphasis on narrative development or world-building. In contrast, home games could develop narrative and the game's world in a more complex fashion, allowing for the emergence of longer-form game structures, such as those of adventure games. The longer amount of time required to successfully complete such home games encouraged a change in gameplay mechanics that allowed players to save their progress after each session of play rather than having to start from the beginning each time the game was played.

Whereas personal computers allowed game data to be saved to a floppy disk or hard drive, home consoles initially lacked the capacity to easily save such information. For example, Nintendo's *The Legend of Zelda* (1986), for the Nintendo Entertainment System (NES), was released on a specially designed cartridge that included a battery to store game data while the system was turned off. This allowed players to save their progress, accumulate possessions in the game, and resume the game later. Subsequent game consoles offered the ability to save

games to memory cards (like the Sony PlayStation) or to hard drives built into the console (like the Microsoft Xbox). Online services such as Xbox Live and Nintendo Switch Online also allow for “cloud saving,” wherein game save data is stored remotely on a server run by the service, allowing players to back up their saved game and restore it from the server, including to a different console or platform.

Early save game functionality in console and computer games was frequently cumbersome to access or use, requiring players to access a specific game menu to save. Some later games intentionally limited the number of times a game could be saved to make the game more challenging, such as Capcom’s *Resident Evil* (1996; also named *Biohazard*). Other games simplified the saving process; for example, Valve’s *Half-Life* (1998) had a “quick save” feature, allowing the player to press a single button to save the game. Save functionality has become a common feature of home video games, and games that use a save function often employ an “autosave” feature that will automatically save a player’s progress at predetermined intervals or portions of the game, much like the similar use of checkpoints in games.

FromSoftware’s action fantasy role-playing game (RPG) *Demon’s Souls* (2009) combines autosaving with restricting the player’s ability as a gameplay mechanic and to make the game considerably more difficult. The game uses a single game save slot and does not allow the player to manually save his or her progress. Instead, the game autosaves when a player completes a level in the game, permanently replacing the existing saved game. Players progress in the game

by defeating enemies and collecting these enemies’ “souls,” which can be used to upgrade the player’s character and items. If a player dies on a given level, all the souls collected since the last save are lost, and a “bloodstain” is left to mark the player’s point of death on the level. The game then autosaves, and the player is sent back to the start of the level and must try to reach the bloodstain to reclaim the souls. If the player fails to do so and is defeated before reaching this bloodstain, the previously accumulated souls are permanently lost, and a new bloodstain and autosave are created. Therefore, the game employs autosaving to overwrite both player successes and failures, making the save function itself a key gameplay mechanic.

Scepter of Goth

Scepter of Goth is a text-based adventure multiplayer game created by Alan E. Klietz that was launched in 1978 under the name *Milieu*. The game was renamed *Scepter of Goth* when it was ported on IBM XT in 1983. It is one of the first massively multiplayer online (MMO) games and was launched the same year as Richard Bartle’s *MUD1*; since *Milieu* was originally a local game, it is difficult to know which came first. *Scepter of Goth*

(*Milieu*) is the first commercial MMO, as *MUD1* was a free game.

Milieu was created by Klietz with the desire to make a multiplayer version of Crowther and Woods's *Adventure* (1977). It was the most popular game on the Minnesota Educational Computing Consortium (MECC). When MECC closed in 1983, the game was ported on IBM XT and renamed *Scepter of Goth*. Klietz then formed the company GāmBit Multi-Systems with new partners to support the new online system.

GāmBit was organized as a franchise system. Each franchise had paying customers (usually charged by the hour) and could support up to sixteen players connected via phone lines. GāmBit charged a franchise fee and took a part of the transaction done by the franchisees. Later, Interplay, one of the franchisees, bought GāmBit and supported the game until it went bankrupt in the late 1990s.

Scepter of Goth's combat and leveling mechanics were inspired by Dungeons & Dragons (D&D; 1974), especially the advanced edition. The character classes (cleric, fighter, lady [female only], magic user, paladin, ranger, thief, and the special classes assassin and barbarian) were also like D&D. The game had a player-versus-player (PvP) aspect, but it had mechanics to discourage powerful characters from killing lower-level characters.

To ensure the survival of the game and to create special, changing adventures, *Scepter of Goth* also used Dungeon Masters (DM). The DMs could, for example, create new monsters and rooms, interact with players, grant wishes to players, and even create new game worlds.

Most of the *Scepter of Goth* took place in a coastal city called Boldhome, which

was surrounded by an ancient empire's ruins. The game also had other worlds, which were mostly created by DMs (e.g., one had a *Dragonlance* setting). The game's goal was to gain the Scepter. When a player gained it, a cataclysm destroyed the game's world, and the game would then restart.

Richard Bartle, in his book *MMOs from the Inside Out: The History, Design, Fun, and Art of Massively Multiplayer Online Role-Playing Games* (2015), says that many MMOG are directly influenced by *Milieu* and *Scepter of Goth* (e.g., *EverQuest* [1999], the *Guild Wars* series, and *Star Wars: The Old Republic* [2011]). He also notes that *Scepter of Goth* is often forgotten when people discuss the history of massively multiplayer online role-playing games (MMORPGs), even though the game had a strong influence on their development, and many game developers have been influenced by *Scepter of Goth* both as players and as DMs.

Scrolling

Scrolling was important to the development of video games because it meant that screen edges no longer had to be the

The first video game to feature scrolling was Kee Games's arcade game *Super Bug* (1977) [left]. The first home computer game with scrolling was Origin's *Ultima* (1980) [right]. (Courtesy of Mark J. P. Wolf)

boundaries where a game's playing field ended; spaces could continue off-screen and be brought on-screen through the process of scrolling, making the discovery of the playing field a part of the game.

The patent for scrolling (United States Patent #4,445,114, "Apparatus for Scrolling a Video Display") was filed by Atari on October 3, 1980, and listed David R. Stubben as the inventor. Scrolling had appeared a few years before, first in *Super Bug* (1977) by Kee Games (a subsidiary of Atari), which featured four-way scrolling (horizontally and vertically), and two-way scrolling appeared in Atari's *Football* (1978), the graphics of which provided the example used in the patent. The first home computer game to feature scrolling was Richard Garriott's *Ultima* (1980), which used a tile-based system: a new row or column of tiles was added as the screen scrolled from one position to the next.

Eight-way scrolling involves a background that can scroll horizontally and vertically at the same time, so the player

character can move northwest, northeast, southwest, and southeast, in addition to the north, south, east, and west movement found in four-way scrolling. Games with eight-way scrolling include the arcade game *Aztarac* (1983) and home console game *Mega Man 3* (1990). Other variations on scrolling continue to appear. For example, in Jason Rohrer's *Passage* (2007), as space scrolls by horizontally, it does not move on-screen and off-screen at the screen's edges but rather compresses or decompresses horizontally on either end, so all the horizontal space is represented on-screen at all times, albeit sometimes in highly compressed form.

Although originally patented for use in video games, scrolling became a common element of the graphic user interface (GUI) of home computers during the late 1980s, with on-screen scroll bars to control the scrolling. Scrolling is now common enough that hardware is designed with it in mind, and computer mice now often feature a wheel that allows the user to scroll the screen directly from the mouse itself. On touchscreen devices such

as the iPhone and iPad, scrolling is accomplished simply by flicking the screen with one's finger, an intuitive gesture that seems to move the screen's image manually. New patents that involve scrolling continue to appear, for example, patent #5,877,760, "User Interface for Synchronously and Independently Scrolling Windows" (filed 1996), and patent #7,428,709, "Multiple-Panel Scrolling" (filed 2005).

SEGA

The company that would become SEGA began in the 1940s. Martin Bromley, with partners James Humpert and Irving Bromberg, started Standard Games in Honolulu. Bromley managed several game rooms on the U.S. Territory of Hawaii that featured slot machines, pin-ball games, and various other coin-operated amusement appliances.

In 1951, when new gambling legislation was passed, the company purchased confiscated slot machines from the

government and shipped them overseas for use by servicemen stationed in Japan. At this time, Bromley decided to move the company to Tokyo. In May 1952, he partnered with American businessmen Dick Stewart and Ray Lemaire and began importing musical jukeboxes; they renamed the company Service Games of Japan, or the Japanese equivalent, Nippon Koraku Bussan. The company became one of the three largest coin-op companies in Japan, competing with Taito and Rosen Enterprises Ltd., with mechanical devices placed in more than five thousand locations on the Japanese islands.

During this same period, Dave Rosen, operating under the name of Rosen Enterprises Ltd., was importing art and other items, such as coin-operated instant photo booths, into Japan. Although very successful, Photorama technology was not patented, and other competitive franchises began to sour the market. Rosen began looking for an alternative luxury product to import. In 1956, Rosen began importing electromechanical games (such as *Deluxe Baseball* [1953]), primarily manufactured stateside by Midway and Williams, which became very popular. In time, arcade parlors began to emerge in Japan.

By the mid-1960s, a large portion of the electromechanical games that were being manufactured were very similar to, or improved updates of, other available games. Rosen recognized that more diversity was needed within the industry, and in 1965, Rosen Enterprises Ltd. merged with Service Games to create SEGA Enterprises Ltd. The combination of the first two letters of each word in the company's name—"SE" from "Service" and "GA" from "Games"—created the

name “SEGA,” which is now known as one of the pioneers of the video game industry.

The new company’s focus was to create original games to be placed in its established locales. Within five years, SEGA was creating approximately ten new games a year and even exporting them to the United States. SEGA’s first release was *Rifleman* (1967), a target-shooting game that featured a rifle mounted to a cabinet. SEGA’s first hit was *Periscope* (1968), a submarine simulator that featured a periscope apparatus that allowed the player to aim and fire torpedoes at targets.

In 1969, the oil giant Gulf + Western acquired SEGA Enterprises, and the SEGA brand became part of the Paramount group, with Rosen remaining CEO of the SEGA division. With new backing, which included a new infusion of cash, SEGA began to grow even larger and faster. SEGA then gained control of Gremlin, a proven American arcade company that had a highly regarded manufacturing division. The Gremlin acquisition allowed SEGA to become a major supplier of games across the United States and Europe. By 1979, SEGA had released more than a hundred electromechanical games, including *Jet Rocket* (1970), a flight simulator regarded by many as one of the finest electromechanical games ever designed.

In the early 1980s, SEGA made the transition into the electronic gaming industry. Examples of early SEGA coin-op video games are the raster-based titles *Astro Blaster* (1981), *Space Odyssey* (1981), and *005* (1981). SEGA also released five vector games, *Eliminator* (1981), *Space Fury* (1981), *Star Trek* (1982), *Tac/Scan* (1982), and *Zektor* (1982). SEGA

began to license, produce, and publish games for home consoles such as the Atari VCS 2600. SEGA arcade titles, such as *Buck Rogers* (1982), *Congo Bongo* (1983), and *Star Trek* (1982), were all released for the Atari 2600. Several SEGA brand games, including *Carnival* (1980), *Turbo* (1981), and *Zaxxon* (1982), were also released for the Mattel Intellivision, the ColecoVision and other home video game systems and home computers.

In 1982, SEGA’s revenues reached \$214 million. As a pioneer in technology, SEGA released several groundbreaking titles, such as *SubRoc-3D* (1982), the first coin-op game with 3-D hardware that delivered a separate image to each eye, creating a stereoscopic effect. SEGA also released the game *Astron Belt* (1982), the first developed arcade laserdisc game.

In July 1983, SEGA entered into the home video game console market in Japan with the release of the SG-1000. Releasing mostly scaled-down ports of SEGA’s arcade games, the SG-1000 was a modest success, and the slightly modified SG-1000 Mark II was subsequently released. SEGA also released the SC-3000 series of home computers in Japan.

During the video game industry crash of 1983, Gulf + Western split SEGA and sold it to two groups: The U.S. commodities were sold to pinball manufacturer Bally, and the Japanese assets were sold for \$38 million to Dave Rosen; Hayao Nakayama, the Japanese head of operations; and multibillion-dollar Japanese conglomerate CSK chairman Isao Ohkawa. This new company structure placed Nakayama as company president and Ohkawa as chairman; Rosen took control of the new American division. In 1984, Japanese giant CSK purchased SEGA.

In Japan, a new SEGA system, the SG-1000 Mark III, was released in 1985. That same year, Nintendo successfully launched the Nintendo Entertainment System (NES), filling the void left empty by Atari in North America, Europe, and Australia. SEGA recognized the opportunity and moved into the console market in the United States for the first time. As a result, the SG-1000 Mark III was renamed the SEGA Master System (SMS) and launched in the United States in 1986 via a distribution deal with Tonka Toys. The SMS reached European shores the following year. By 1986, SEGA stock was being traded on the Tokyo Stock Exchange. Hit titles, which later became SEGA franchises, were born, including *Shinobi* (1987), *Phantasy Star* (1988), and *Alex Kidd* (1986); the main character of the latter, Alex Kidd, became the unofficial SEGA mascot.

SEGA released the SEGA Mega Drive in Japan in 1988 and in the United States in 1989, with the name changed to the SEGA Genesis, due to a trademark dispute. SEGA initially negotiated with Atari to market the console in the United States, but, failing to come to agreeable terms, successfully released the Genesis in North America itself, packaged with a copy of the popular arcade game *Altered Beast* (1988). The initial marketing campaign against rival and market share leader Nintendo involved personality licensing. SEGA positioned itself against the competition with the likes of Evander Holyfield, Michael Jackson, Tommy Lasorda, Joe Montana, Pat Riley, and other well-known sports figures and celebrities. It also launched the successful “Genesis Does What Nintendon’t” campaign.

SEGA also chose to challenge the Nintendo Game Boy portable handheld

game system. In 1990, the SEGA Game Gear handheld console was released in Japan; most other regions saw a release the following year. Unlike the Game Boy, it had a color screen. The Game Gear was very similar in design to SEGA’s own Master System home console. As a result, many SMS games were converted for play on the Game Gear, and a device called the Master Gear Converter allowed for actual Master System cartridges to be played on the Game Gear. Although more successful than other handheld competitors of the time, such as the Atari Lynx or NEC’s TurboExpress, the Game Gear still failed to capture the market from Nintendo’s Game Boy.

Nintendo had Mario to market its brand, and SEGA needed a similar mascot because Alex Kidd and other SEGA franchises could not compete. Realizing that Nintendo’s initial demographic was aging, in 1991, SEGA created Sonic the Hedgehog, a new character aimed at the teenage market, and a game with Sonic was bundled with the new system. Within a year, Sonic the Hedgehog became so popular that he was the first and only non-Disney character at Disney theme parks. SEGA started screaming its brand name at the end of every advertisement, and the “SEGA Scream” was born.

SEGA reached its peak in the early 1990s. The arcade market was profitable, and *Sonic the Hedgehog 2* (1992) on the SEGA Genesis sold more than six million copies. In North America, SEGA controlled 65 percent of the video game market (GamertechTV 2010). In 1992, SEGA introduced new peripherals for the SEGA Genesis, the CD-ROM-based Mega CD, also known as the SEGA CD, which paired an additional CPU with a CD-ROM drive. With the SEGA CD, the

Genesis could play full-motion video (FMV), perform scale and rotation effects to sprites, provide a larger color palette, play CD-quality audio and CD+G-enhanced audio CDs, and store massive amounts of data compared to cartridges. SEGA touted its technology advancement with its “Welcome to the Next Level” campaign.

But the introduction of the SEGA CD split SEGA’s user base, brand focus, and resources. At \$300, the SEGA CD was relatively expensive, and most developers at the time were unprepared and ill-equipped to deal with the new technology. As a result, few developers took advantage of the second CPU and mainly just ported previously existing software with minor upgrades, such as improved audio or inserted FMV cutscenes, most of which failed to improve gameplay.

In 1994, SEGA launched the SEGA Channel, a cable television network. Subscribers were supplied with an adapter that fit into the SEGA Genesis cartridge slot by their local cable company. This adapter allowed users access to fifty games, some unique to the service, and was unavailable in retail outlets. At one time, the SEGA Channel had a quarter million pay subscribers.

Also in 1994, the SEGA Saturn was released in Japan, and its release in the United States was planned for Saturday, September 2, 1995, dubbed “Saturnday.” However, that date was a ruse, and the SEGA Saturn was actually launched on May 11, 1995, for \$400. The announcement occurred during the Electronic Entertainment Expo (E3), to the surprise of the industry, including up-and-coming competitor Sony. It was so much of a surprise that many retailers, such as Walmart and KB Toys, were left out of

the early launch. Angered by this exclusion, many vendors refused to carry the system. Game publishers were also caught off guard by the revelation, and, as a result, little software was available for the Saturn release. Despite having a four-month lead over the Sony PlayStation, the Saturn only sold eighty thousand consoles before Sony’s release date. The PlayStation sold one hundred thousand consoles at launch, partially because of its cheaper price point, which was a full hundred dollars less than the Saturn.

Although the Saturn was just as powerful as Sony’s machine, it was more difficult for developers to program with because it had two separate central processing units (CPUs) and six other processors. The initial design for the system only had one CPU, but when SEGA learned of Sony’s PlayStation specifications, it added a second processor to try to leapfrog the competition technologically. In the end, the move to make a better console resulted in lower-quality software and longer development times, leading to delays. As a result, Sony became the market leader as the Saturn slowly lost ground.

Following the heyday of the Genesis, patrons began to lose confidence in the SEGA brand. Although the last three generations of SEGA platforms (SEGA CD, 32 X, and Saturn) were not exactly failures, they were not as successful, by any means, as SEGA or consumers had hoped. In late 1998, SEGA launched its final hardware platform, the SEGA Dreamcast, which was the first console to include a built-in modem supporting online play, including voice chat. When the Dreamcast launched in the United States on September 9, 1999 (9/9/99), it

sold more systems in twenty-four hours than any game platform in history, with a staggering 225,132 units sold. Within two weeks, it more than doubled that number to over a half million units, a milestone for the time, making it the most successful hardware launch in history.

The Dreamcast held its own for two years until Sony launched the Sony PlayStation 2 in the winter of 2000. Although SEGA continued to support the Dreamcast until 2002, it announced that it was leaving the hardware industry and becoming a third-party software publisher. To date, SEGA brand games are available for most gaming platforms, including the Microsoft Xbox One, the Nintendo Switch, and the Sony PlayStation 4.

SEGA CD/Mega-CD

The SEGA CD was an add-on peripheral that allowed CD media software to play on a standard SEGA Genesis cartridge-based console. It premiered in Japan as the Mega-CD in December 1991, connecting to the Japanese Genesis equivalent, the SEGA Mega Drive. It was originally designed to compete with the NEC PC-Engine (named the Turbografx-16 in the

United States) CD unit, a popular platform in Japan. However, after reaching the market, its primary competition became the Super Nintendo Entertainment System (SNES), especially in the Western Hemisphere.

The SEGA CD was released in the United States beginning in late October and early November 1992. Priced at \$299.99, the SEGA CD unit was more expensive than the SEGA Genesis unit itself. SEGA sold all 50,000 SEGA CD units produced in the first run within three weeks, selling out just before the Thanksgiving holiday. The second run of 150,000 units was released just in time for Christmas on December 22. To put this in perspective, the Japanese Mega CD sold about 100,000 units in its first year; the U.S. release had doubled the Japanese sales in a quarter of the time. The initial success of the SEGA CD in the United States looked promising for SEGA and its CD-based device.

The advantages gained by connecting the SEGA CD unit to the SEGA Genesis were many. Graphically, it allowed the Genesis to perform such computations as ultrasMOOTH scaling and biaxial rotation of sprites using an ASIC graphics processor. It also made interactive movies possible by allowing the Genesis to run full-motion video (FMV). Greatly improved audio was also an obvious benefit of compact disc (CD) media.

CD-ROMs could also hold much more data than the traditional cartridges of the time. Most cartridge games were 1 to 4 megabytes in size, whereas a SEGA CD-ROM could hold more than 650 Mb of game data. Expanded memory space meant more features and game improvements. Memory in the early 1990s was very expensive, so CD-ROM manufacturing,

even though it was relatively new to the industry, was substantially cheaper than manufacturing a cartridge.

The technology behind the SEGA CD consisted of its own central processing unit (CPU), the Motorola 68000. This CPU ran parallel with the SEGA Genesis 68000 CPU, combining both CPUs to perform functions. It doubled the Genesis system memory and enabled larger color palettes (128 using hold and modify [HAM] techniques or 256 colors for FMV content) to be used above the regular Genesis 64 color palette.

Two models were released over the SEGA CD's life span. The initial model released in November 1992 featured a front-loading door and was mounted below the Genesis unit, connected via the interface slot located on the right of the console. A second model was released in 1994 for \$230. This unit was designed to connect to the second Genesis console that was smaller in size and positioned itself to the right of the Genesis unit. This model also replaced the front-loading interface with a manually opened door.

Other devices that would play SEGA CD games included the JVC X'Eye (WonderMega in Japan) and SEGA's own CDX, both of which were stand-alone units that played SEGA Genesis and SEGA CD software. Pioneer released the LaserActive platform, which was modular in design and allowed SEGA software to play on the device with the insertion of a SEGA Module. This module also allowed special laserdisc games to be played using the SEGA hardware. Perhaps the most unusual and rare of the SEGA CD units is the Aiwa CSD-G1M Mega Drive boom box, which was only released in Japan. This portable stereo had a radio and could play audio CDs

and cassette tapes in addition to Mega Drive and Mega CD video games.

The SEGA CD came bundled with the FMV title *Sherlock Holmes Consulting Detective*, a space shooter called *Sol-Feace* (1992), a compilation disc with four classic SEGA titles (*Columns*, *Golden Axe*, *Shinobi*, and *Streets of Rage*) and two CD+G music sampler discs. The short-lived CD+G format, short for CD+Graphics, was a format that played graphic images while playing music from the CD, similar to the traditional slideshow.

The SEGA CD had support from many third-party developers and publishers, including such proven companies as Data East, Konami, Vic Tokai, and Working Designs. Even Sony Imagesoft and Psygnosis, supporters that later became SEGA's rivals in the industry, created content for the SEGA CD. Two publishers, Digital Pictures and Midway, thrust the SEGA CD into the limelight unwittingly. Unfortunately, the publicity was negative and affected sales of the SEGA CD to some degree. Violence in gaming had become controversial since the release of Exidy's *Death Race* (1976), but with the advent of FMV gaming, a new level of realism had entered into the industry. Digital Pictures revived an old project originally created for Hasbro's unreleased Project NEMO for the SEGA CD under the name *Night Trap* (1992). Because the game had some questionable material, it became one of the centerpieces of a congressional investigation concerning violence in video games. Paired with the negative press concerning Midway's *Mortal Kombat* (1992), also available for the SEGA CD, the hearings that began on December 9, 1993, scared parents just at the height of the Christmas shopping season.

Night Trap was not the only FMV title released for the SEGA CD. In fact, the SEGA CD became known as the system for FMV games. Digital Pictures also resurrected another old NEMO game, *Sewer Shark* (1992), and created new FMV content. Many companies believed FMV to be the future of gaming and invested heavily in the new technology. SEGA was so involved that it created its own movie studios to create FMV gaming content. The market behaved differently, and after poor reviews of FMV-style games by trade and consumer magazines, followed by poor sales, the fanfare quietly died, taking the SEGA CD along with it.

Production of the unit was suspended in December 1995. After four years on the market, the SEGA CD sold 2.5 million units in the United States and approximately 6 million units in total worldwide. Because the Genesis sold approximately 29 million consoles, it is evident that about 20 percent of Genesis/Mega Drive owners chose to upgrade their Genesis consoles with a SEGA or Mega CD. More than 150 games were released for the SEGA CD platform. *Shadowrun* (1996) was the final official game released for the Mega CD, until Good Deal Games revived publishing on the SEGA CD platform in December 2000.

SEGA Dreamcast

The SEGA Dreamcast was a sixth-generation 128-bit home video game console. It was released on October 27, 1998, in Japan; on September 9, 1999, in North America; and on October 14, 1999, in Europe. A last-ditch effort to reinvent the company image and distance itself from the earlier string of failures—specifically, the abandoned SEGA Genesis add-ons, SEGA CD and 32X, and the poorly selling SEGA Saturn—the system was SEGA’s final foray into the home console market.

The Dreamcast featured a Hitachi SH-4 CPU, operating at 200 MHz. Its NEC PowerVR2 128-bit graphics chip offered a peak rendering rate of three million polygons per second, maximum resolution of 640-by-480 pixels, 24-bit color, and hardware support for alpha blending, perspective correction, anisotropic, bilinear and trilinear mip mapping, Gouraud shading, bump mapping, z-buffering, and anti-aliasing. The system had 16 MB of main memory, 8 MB of video memory, and 2 MB of sound memory. The Yamaha AICA Sound Processor provided sixty-four sound channels, with 3-D sound support. Software was distributed on GD-ROMs, SEGA’s proprietary high-density optical discs, with a capacity of 1.2 GB. The Dreamcast was the first console to provide out-of-the-box online connectivity with a built-in modem (which was later superseded by a broadband adapter).

The system received a wide variety of peripherals, including a mouse and a keyboard, as well as a number of specialized controllers, such as a fishing rod controller (supported by several fishing games), motion-sensitive maracas (for

use with *Samba de Amigo* [2000]), and a dual analog joystick (bundled with *Cyber Troopers Virtual-On: Oratorio Tangram* [1999]).

Of note was the Visual Memory Unit (VMU). Essentially a 128 KB memory card, it also featured a small 48-by-32 monochromatic LCD display, a speaker, a directional pad, and four buttons. A number of Dreamcast titles included minigames that could be downloaded into the unit, which could then be used as a simple handheld game console.

SEGA allocated a \$500 million budget for the development and marketing of the console; in an effort to not repeat the mistakes made with the Saturn, approximately half of that sum was directed toward the promotion of the new system. In Japan, after a strong launch, sales dropped off quickly, especially after the announcement of the Sony PlayStation 2 (PS2). In the wake of PS2's release, the system was largely ignored. The Dreamcast's U.S. debut, however, was a spectacular success. With more than 225,000 units sold within the first twenty-four hours, it was considered the most successful launch in video game history.

But SEGA was not able to sustain the initial momentum. Its track record of prematurely discontinuing support for its consoles fostered wait-and-see attitudes among buyers and third-party developers alike (e.g., Electronic Arts [EA]—a major contributor behind the success of the SEGA Genesis—declined to support the platform at all). Other contributing factors included SEGA's continued reliance on arcade ports and underutilized online connectivity (although the SEGANet service was operational since launch day, the software was delayed, and the slow speed of

the built-in modem was also a problem). Finally, Sony's strong brand name and the hype surrounding the PS2 also served to divert attention away from SEGA's console. Interest in the Dreamcast waned despite price cuts, and in mid-2000, SEGA dropped the system's price to \$149; shortly thereafter, it offered a \$150 mail-in rebate with two-year SEGANet subscriptions. Sales spiked but did not substantially increase the system's market share.

With the discontinuation of the Dreamcast in 2001, SEGA withdrew from the home console market and shifted to third-party game development. Independent games for the Dreamcast are developed to this day. Notable Dreamcast games include *Soulcalibur* (1999), *Shenmue* (1999), *Samba de Amigo*, *Phantasy Star Online* (2000), *Rez* (2001), and *Ikaruga* (2002).

An interesting outgrowth of the Dreamcast technology was the SEGA NAOMI (New Arcade Operation Machine Idea) arcade system board. Unveiled in 1998, this low-cost alternative to expensive arcade platforms was effectively a Dreamcast with expanded main memory and video memory. Hardware similarities made conversion between the two platforms simple, with popular titles ported to Dreamcast after a successful arcade run. In 2000, the NAOMI board was succeeded by the NAOMI 2 board.

SEGA Game Gear

The SEGA Game Gear, released in Japan in 1990, was Sega's first portable console. With its 32-color backlit LCD screen, 8-bit Z-80A processor, and the ability to output stereo sound through headphones, the Game Gear sought to upstage rival portables on the basis of its technical specifications. The Game Gear's primary competition was the Nintendo Game Boy, a console that, despite its ostensibly "withered" (or "seasoned") specifications (see Reynolds 2016), had established something of a monopoly in the burgeoning market for handheld games. The Game Gear's software catalog largely consisted of ports of games originally developed for SEGA's Master System home console, including *Sonic the Hedgehog* (1991) and *Land of Illusion Starring Mickey Mouse* (1993).

Although it had a commercial life that lasted until at least the year 2000 (SEGA officially withdrew support for the console in 1996), and although it purportedly sold nearly eleven million units worldwide, the Game Gear was (and still is) regarded as a "failure" by many magazines (Sato 1998) and websites (Buchanan 2008). Like most portable consoles from the past two decades (including, e.g., the Atari Lynx, the NEC TurboExpress, and the Sony PlayStation Portable [PSP]), the Game Gear was unable to meaningfully challenge Nintendo's long-standing dominance in the portable video game market

(as opposed to the mobile video game market [see McCrea 2011]).

The Game Gear is nonetheless a console that poses problems for "Wikipedic" accounts of video game history. It fulfilled almost every expectation that could be had of a handheld console in the early 1990s, yet it was unable to dislodge the Game Boy. "If you're thinking about a hand-held system," wrote the editors of *SEGA Visions* in 1991, "Game Gear should be your hands-down choice. Game Gear has a big 3.2" screen, color that will knock your eyes out, and graphics and animation that will stand up to your home video game system" (Ninsen and Harris 1991, 4). The Game Gear's "failure" is often attributed to its hardware design (specifically, its short battery life) and its limited software catalog. Yet, as media historians have long noted, perceived hardware and software shortcomings are rarely determining factors when it comes to the success or failure of any given technology (much as price is rarely a determining factor; see Lipartito 2003, 59). Success and failure are better understood as social constructions—shared values, expectations, aspirations, and apprehensions—that come to be assigned to particular technologies in any given cultural period or context (see Marsden 1988; Vermeir 2006; Boyer 2009; Arsenal 2017). "Alter any number of circumstances," writes Kenneth Lipartito (2003, 76), "and failure might have been a success"—such a statement rings true for the Game Gear.

The Game Gear was explicitly developed and marketed to appeal to long-standing *fantasies* in video game culture; namely, the fantasy of a full-color backlit portable device capable of adequately reproducing venerated titles such as *Sonic*

the Hedgehog in handheld form. Despite not selling as many units as Nintendo's Game Boy, it still performed important narrative work for game history by preparing ground for the various full-color portable consoles that came after its release.

Like many technologies released in the 1990s, the Game Gear suffers from "capacitor plague," meaning that its capacitors are prone to leaking, bursting, or generally becoming weaker over time, which can compromise (or completely debilitate) the console's sound output and display. However, fans have created numerous online how-to guides for replacing the console's capacitors, ensuring that the Game Gear continues to enjoy a commercial afterlife. The console has inspired various homebrew projects, such as the recently released *Swabby* (2016) from Hang-On, a game that remediates assets, sprites, and backgrounds from Game Gear titles such as *Sonic the Hedgehog* and *Shinobi* (1991).

SEGA Genesis/SEGA Mega Drive

The SEGA Mega Drive was a fourth-generation video game console. It was released in Japan on October 29, 1988; in North America (as SEGA Genesis) on August 14, 1989; and in Europe on November 30, 1990.

The SEGA Genesis, also known as the SEGA Mega Drive. (Robtek/Dreamstime.com)

Positioned as a direct competitor to the Nintendo Entertainment System (NES) and NEC PC-Engine/TurboGrafx-16 and marketed as the first “true” 16-bit console (a jab at the latter’s hybrid 8/16-bit architecture), the Genesis/Mega Drive was SEGA’s attempt to bring arcade-quality games to a home system. The hardware design was based on the company’s successful System-16 arcade board. The similarities between the two platforms allowed for easy conversion of existing arcade titles, giving the system access to a considerable library of popular, recognizable games.

The system was based on a 16/32-bit Motorola 68000 CPU, operating at 7.67 MHz, and was equipped with 64 KB of main memory, 64 KB of video memory, 8 KB of secondary memory, and 8 KB of sound memory. The Zilog Z80 chip served as the primary sound controller (providing up to ten sound channels) and provided backward compatibility with the SEGA Master System (SMS). The dedicated video display processor (VDP)

could display graphics in up to 64 colors from a 512-color palette, at the maximum resolution of 320-by-224 pixels. Games were distributed on cartridges.

Although it was not very successful in Japan, the system became a great hit in the United States and Europe, where it was marketed as an “edgy” and “cool” alternative for older consumers. Under the “Genesis Does What Nintendon’t” slogan, the American advertising campaign emphasized the software library aimed at a more mature audience, including numerous arcade-quality games as well as sports games endorsed by popular athletes (e.g., *Tommy Lasorda Baseball* [1989] and *Joe Montana Football* [1991]).

It was not until the 1991 release of *Sonic the Hedgehog*, however, that the system finally received its “killer app” (an application that consumers buy a system to obtain). The fast-paced platform game was SEGA’s response to Nintendo’s *Mario* series, its eponymous character designed to provide the company with an instantly

recognizable corporate mascot. *Sonic* proved highly popular and soon replaced the arcade port *Altered Beast* as the system's pack-in title. This move, in combination with intensified advertising efforts, led to an exponential increase in sales. By 1992, SEGA held a 55 percent share of the U.S. 16-bit market. The console enjoyed similar popularity in Europe; in Japan, however, it remained at a distant third place behind the Super Nintendo Entertainment System (SNES) and the PC-Engine.

The Genesis/Mega Drive received a number of accessories, most notably the Power Base Converter (an adapter for SEGA Master System cartridges), the SEGA CD/Mega CD add-on, and the 32X expansion unit. Initially conceived as an entirely new platform, the 32X was eventually adapted into an expansion pack intended to fend off competition from the SNES and extend the market life of the system until the SEGA Saturn gained sufficient momentum. Equipped with two 32-bit RISC processors, a more powerful VDP, and an additional 512 KB of memory, the unit added support for three-dimensional graphics and increased the number of on-screen colors to 32,768. However, developers quickly abandoned the 32X in favor of the Saturn. Only about forty games were released, many of them enhanced ports of existing titles. Despite price drops, the expansion was a commercial failure. It was discontinued along with the SEGA CD in 1995.

In addition to SEGA's original Genesis/Mega Drive and the slightly revised Genesis 2/Mega Drive 2, the system was also available in a wide variety of variants and derivations, manufactured by SEGA or its licensees (including, e.g., the SEGA Multi-Mega/CDX, the handheld SEGA Nomad,

Majesco's Genesis 3, the JVC Wondermega/X'eye, and the Amstrad Mega PC).

The Genesis/Mega Drive was discontinued following SEGA of Japan's decision to focus attention on the SEGA Saturn. The system was supported in Europe and Brazil until 1998. With approximately thirty million units sold worldwide, it was the second-best-selling console of the fourth generation (following the SNES) and SEGA's most popular home system.

SEGA Master System/SEGA Mark III

The SEGA Master System (SMS) premiered in Japan as the SEGA Mark III in 1985. The machine was only intended for the Japanese market, until Nintendo successfully launched the Nintendo Entertainment System (NES) in North America. Seeing the success of the NES

overseas, SEGA decided to compete, and in June 1986, the SMS debuted in the United States with a \$200 price point.

Games for the Master System were available in two formats. The traditional media for console gaming at the time was the cartridge, and that was also the primary software delivery format for the SMS. A typical SMS cartridge could hold up to 4194 KB of memory. However, cartridges were expensive to manufacture, so for simpler titles that required less data, a cheaper alternative was available. This format, which could hold a maximum of 256 KB, was referred to as a “SEGA Card” because it resembled the approximate size and shape of a credit card.

Although the Master System had the usual lot of accessories, such as a sports pad roller controller, light phaser, and alternative controllers, SEGA also issued the SEGAScope 3-D Glasses, which were very high quality and offered quite an immersive experience for the six games that were compatible with the device. It was far superior to the anaglyphic 3-D system that used red and blue filtered lenses commonly used for 3-D movie viewing since the 1950s (see 3-D Hardware). The SEGAScope 3-D accessory actually used a shutter system synced to the graphics presented on the television screen.

One Master System strength was the ports of popular SEGA arcade titles, such as *After Burner* (1988), *Hang On* (1986), *Shinobi* (1988), and *Space Harrier* (1986). SEGA’s unofficial mascot of the time was Alex Kidd, which appeared in four separate games for the SMS, before making the transition to the SEGA Genesis and being retired and replaced with Sonic the Hedgehog. The Master System

also launched one of SEGA’s most beloved franchises by releasing *Phantasy Star* in 1988. The *Phantasy Star* series has since spawned more than a dozen games and continues to receive new iterations almost annually.

A SEGA Master System II was also released. This console was not an entirely new system but a cosmetically redesigned SMS created to lower the unit cost and allow the system to be marketed for a longer period of time. The SMS II’s compatibility with cartridge media was excellent, but the new hardware lacked the ability to play the SEGA Card software (which was rarely used) as well as other minor changes and omissions.

The SMS was unable to compete against the NES in the United States. Nintendo’s dominance was roughly 90 percent of the video game industry, with only 10 percent remaining for the SMS and the Atari 7800 to share. There are many possible reasons why the Master System failed to compete in the United States. Distribution and marketing were initially done by Tonka; although this move was originally done to help the Master System reach the public, it is possible that it actually hindered its availability and hurt retail sales. In 1990, SEGA of America reacquired the SMS rights, but promoting the Master System became less of a priority for SEGA with the new SEGA Genesis console on the market, which was performing strongly.

Lack of third-party support certainly harmed the Master System. Nintendo had exclusive contracts with most software developers at the time, which prevented them from making software for rival companies, including SEGA. Because many of these contracts were signed before the Master System even hit

the market, and because the SMS had such a small market share, few third parties even took notice. A console is only as good as its software; with the SMS library paling in comparison to the massive Nintendo library, it was definitely debilitating.

Although the Master System did not fare well in the United States, it was more successful in other markets, such as Europe, Australia, and Brazil. The United States only received a fraction of the games for the SMS; domestically, 114 titles were released, whereas an additional 232 games were released overseas. Thus, less than half of the 346 available games were released in the United States.

When SEGA retired the SMS in 1992, the hardware and some games lived on. The Power Base Converter was a device that allowed SMS games to be played on its bigger brother, the SEGA Genesis. The legacy continued when SEGA released its first portable system, the SEGA Game Gear. The Game Gear was basically a portable SMS with minor enhancements, and the Master Gear peripheral allowed Master System games to be played on a Game Gear.

Although the SEGA Master System never reached its full potential, it did pave the road for SEGA to infiltrate the market and transition from a software company making software for other home hardware manufacturers to a consumer electronics hardware company. The Master System certainly taught SEGA many lessons that proved fruitful when launching its next hardware platform, the SEGA Genesis, which became its most successful console.

SEGA Saturn

The SEGA Saturn was a fifth-generation 32-bit home video game console. Released on November 22, 1994, in Japan; on May 11, 1995, in North America; and on July 8, 1995, in Europe, the system was SEGA's attempt at securing an early hold on the emerging 32-bit market and regaining an advantage over Nintendo.

Originally envisioned as a two-dimensional-oriented machine with secondary three-dimensional capabilities, the Saturn was radically redesigned in response to the announcement of the Sony PlayStation. The system was built around two Hitachi SuperH-2 32-bit RISC processors, operating at the speed of 28.63 MHz. Its dual custom video display processor chips could render up to five hundred thousand polygons per second, at the maximum resolution of 704-by-480 pixels, and could simultaneously display thirty-two thousand colors from a 24-bit color palette. The Saturn Custom Sound Processor, controlled by a Motorola 68CE000 chip, provided up to thirty-two channels of PCM playback (CD-quality sound) and up to eight channels of FM synthesis. The Saturn had 2 MB of main memory, 1.5 MB of video memory, and 512 KB of sound memory and was equipped with a double-speed CD-ROM drive. The system's complex

architecture, with two CPUs and six other processors, made it notoriously difficult to program, especially as the twin processors did not operate in parallel but rather competed for memory access.

The Japanese launch was a success, with approximately 170,000 units sold on the first day alone. However, the North American release date was rescheduled from September to May to gain market advantage over the coming PlayStation. Rushed to the market, with its early surprise release date, the Saturn received virtually no promotion. To make matters worse, few games were available at launch because many third-party titles, developed with the original timeframe in mind, were still unfinished. The relatively strong initial sales tapered off quickly. By the time of PlayStation's September 9 launch, the Saturn had only sold around 80,000 units—a number Sony's console easily surpassed within the first week.

Launched at \$399, the system cost \$100 more than the PlayStation. The complex hardware made cost-saving revisions difficult; as a result, the Saturn's price was not lowered in pace with those of the competing 32-bit systems. In addition, the game offerings were perceived to be out of touch with the market. Playing to its perceived strength, SEGA continued to rely heavily on arcade ports rather than console-specific titles. Moreover, the reluctance of the company's American branch to release role-playing games (RPGs) and games with two-dimensional graphics ensured that many of the most successful Japanese titles never made it to the United States. SEGA's ailing reputation, heavily undermined by the SEGA CD and 32X fiascos (see **SEGA Genesis/SEGA Mega**

Drive), and Sony's aggressive promotion of the PlayStation also contributed to the Saturn's weak market performance. Throughout its life, the system remained at a distant third place behind the PlayStation and the Nintendo 64.

The announcement of the SEGA Dreamcast at the 1997 Electronic Entertainment Expo was widely received as the Saturn's death knell. Hardware and software sales dropped sharply. As a consequence, a number of third-party titles, planned or already in development, were canceled, further contributing to the system's decline. The Saturn was discontinued in the United States in 1998; in Japan, a stronger customer base kept it alive until 2000. Notable Saturn releases include *NiGHTS: Into Dreams...* (1996), *Shining Force III* (1997, 1998), *Guardian Heroes* (1996), *Virtua Fighter 1* and *2* (both 1995), *Virtua Cop 1* (1995) and *2* (1996), the *Panzer Dragoon* series (1995–98), *Radiant Silvergun* (1998), and other 2-D shooting games as well as a number of two-dimensional fighting games.

Serious Games

A *serious game* is a game that has been designed for a reason other than to just

entertain. The term has been applied to game development in fields such as business, education, medicine, science, and the military. The term itself has been credited as far back as 1970 to Clark Abt, who wrote a book called *Serious Games*. There were no commercial video games in 1970, but Abt used the book to argue for games that were not intended primarily as amusement but had specific educational goals.

The term regained prominence in 2002 when the Woodrow Wilson Center for International Scholars created the Serious Games Initiative. Shortly thereafter, the term was picked up by multiple authors. For instance, Zyga (2005) defined a *video game* as “a mental contest, played with a computer according to certain rules for amusement, recreation, or winning a stake” (25). He differentiated a serious game as the same mental contest, but one that used the entertainment to further specific objectives (such as health, education, or communication).

There is not one clear definition of serious games. As authors attempt to further define *serious games*, they often end up creating new terms based on the context of use. For instance, *advergaming*, *edutainment*, and *exergaming* refer to the use of games beyond simple entertainment in the respective fields of advertising, education, and health and wellness. *Gamification* refers to the notion of applying game mechanics to nongame settings for the purpose of improving outcomes. *Smart gaming* can be defined as the use of higher-order thinking and strategies, both individually and in multiplayer games, to achieve game objectives. *Social impact gaming* is the use of games to achieve a desired social change.

Given this variation in definitions, there is also great variability and argumentation as to when serious games first appeared. Arguably, serious game development began in earnest in the mid-2000s, timed with the rise in popularity of both the ideas and the terms. One example of a serious game is *Darfur Is Dying* (2006); in the game, participants must find ways to keep their refugee camps running. Along the way, they learn about the genocide in Darfur and ways to help humanitarian efforts. A second example is *Re-Mission* (2006), a game that teaches people about cancer. Researchers (Kato et al. 2008) found that playing *Re-Mission* increased adolescent and young adult treatment adherence, self-efficacy, and knowledge about cancer. A final example is *Superbetter* (2012), a game developed in response to Jane McGonigal suffering depression and suicidal thoughts after having a concussion. The product is an attempt to help people overcome challenges.

Recent research has provided evidence for the importance of serious games in learning and teaching about topics ranging from social skills to behavior change (Boyle et al. 2016). For instance, there is recent evidence that the use of serious games stimulates brain activity. De Freitas described one study in which game players had whole-brain activity compared with formal learning in which only limited brain activity occurred. “Other studies are showing how mirror neurons (premotor neurons) fire both when a person acts and when that person observes the action performed by someone else. In this way, the neuron mirrors behavior as though it were doing the action itself, which might help to explain why simulation and imitation with an emphasis

upon visual data are such powerful learning tools” (De Freitas 2009, 26).

Shareware Games

With the widespread arrival in the early 1980s of personal computers—the IBM PC, Apple II, Commodore 64, and others—home computer games became a burgeoning commercial industry. It was an acutely entrepreneurial period, and many hobbyist programmers were curious about selling their games or showcasing them in an effort to land a full-time job in the new industry. Several groundbreaking games of the period that we know as commercial titles actually began as amateur efforts, including *Rogue* (1980), *Lode Runner* (1983), and the *Zork* series (1977–80). Along the road from

Above: *Beast* (1984), a surprisingly fluid action game, given its ASCII text-based graphics. Below: The turn-based tank game *Scorched Earth* (1991-1995) is best known for its “hot-seat” two-player mode. (Courtesy of Mark J. P. Wolf)

amateur to professional came a new pit stop known as *shareware*, a distribution method that encouraged players to pay through a mixture of community goodwill and “try before you buy” up-sell advertising. With an air of the communal camaraderie that characterized early software development in the university time-sharing labs of the 1960s and 1970s, shareware attracted hobbyist developers ambivalent toward the business of professional software and distribution. Shareware developers sought commercial compensation for their work, but for the vast majority, these proceeds would not be (nor were they intended to be) a primary source of income.

Shareware distribution entails the release of two variants of a program: the *free* (or *demo*) version, which is available without payment and encourages its own copying and redistribution by users, primarily relying on word-of-mouth marketing, and the *registered* (or *paid*) version, which usually improves upon the free with additional features or documentation. Shareware’s free distributions often exhort the user to register for the *full* version by sending payment directly to the author. In the pre-World Wide Web of the 1980s and early 1990s, most shareware (both games and more general applications) could be registered for anywhere between \$5 and \$50, a fee commonly delivered as a check or even cash via postal mail. Diskettes, a game manual, or a registration code for the full program were delivered in return. Shareware up-sell “marketing” ranged from amateur salesmanship promising more advanced capabilities, to appeals to the user’s desire to contribute to a community of grassroots software development, to outright pleas for compensation.

Shareware’s cousin, *freeware*, indicates that the full version of the program is available without a registration fee, and payment, although often requested for goodwill, is even more discretionary. Shareware and freeware are often discussed together, but freeware retains a greater association with hobbyists, whereas shareware is considered entrepreneurial. The shareware concept is generally attributed to a trio of developers, each of whom created important early business programs: Jim Knopf’s database software *PC-File* (1982); Andrew Fluegelman’s *PC-Talk* (1982), a networking program for using dial-up modems; and Bob Wallace’s *PC-Write* (1983), a word processor. Despite its office software roots, however, PC game programmers quickly took up the form and began releasing shareware and freeware in the mid-1980s.

David Clark’s *Sopwith* (1984) for the IBM PC is illustrative of shareware’s tenuous commercial status. Clark was a programmer at BMB Compuscience, a Canadian database and networking company, when he wrote the popular World War I-themed game that was influential in establishing the side-scrolling aviation subgenre. He included a multiplayer mode alongside the four-color CGA graphics to demonstrate BMB’s just developed PC networking technology, Imagnet. Although for-profit, BMB was not a game company, however, and *Sopwith* was given away for free to promote Imagnet at trade shows. Decades later, the game has maintained a devoted following—Clark released a definitive “author’s edition” in 2000—whereas the proprietary Imagnet is an obscurity known only from the history of the game. *Sopwith* is a lesson in the difficulty of

technological prediction, and the influence of programmers' personal interests on the products of their employers.

An early freeware highlight is *Beast* (1984), developed by Dan Baker, Alan Brown, Mark Hamilton, and Derrick Shadel, an elegantly simple action game in which the player manipulates a dense playing field of green blocks, pushing and pulling apart walls in an effort to crush the enemy "beasts" between them. Using the technique of ASCII *text graphics* established by *Rogue* and others, *Beast* achieves a level of animated fluidity that is unexpectedly effective for an early PC with limited graphics hardware. *Beast's* title screen reads, "This is a free copy of BEAST. You may copy it and give it away. If you enjoy the game, please send a contribution (\$20) to Dan Baker." Another example is Wendell Hicken's turn-based tank fighter *Scorched Earth* (1991), one of the best-loved PC shareware games of all time; it is particularly well known for its "hot-seat" multiplayer mode, in which players alternate turns in front of a single computer. Like many popular shareware and freeware titles, *Scorched Earth* succeeds by limiting its ambitions, catering to the particular (and often restrictive) capabilities of the early PC, opting for a stripped-down graphical style: a single-screen, side-view mountain range done up in a handful of bright, saturated colors.

Without an established retail infrastructure, shareware relied on informal trading and distribution through word-of-mouth networks, both digital and social. For PC shareware and freeware, the predominant distribution channel was the dial-up modem bulletin board system (BBS). These pre-Web communities were typically hosted on individual

home computers, which other modem-equipped PCs could network with by dialing in over a standard phone line. This reliance on the landline phone network made most BBSs local in scale, although some did achieve regional or national reach via long-distance calls. As the name indicates, BBSs began as sites for discussion, providing a semipublic forum in which users could share knowledge and software. Because they were usually hobbyist projects themselves, the BBS phenomenon provided a natural affinity with shareware and freeware games. In addition to acting as way stations for the trading of game files, many BBSs also hosted their own games. BBS *door games* (so-called because of the manner in which the BBS host software ran additional programs "on the side") such as *Solar Realms Elite* (1990) and *Trade Wars 2002* (1986) pioneered multi-player networked play long before other platforms.

In the 1980s, most shareware was created and distributed by individual programmers at home, on evenings and weekends, or on borrowed time from work or school. Registration fees were a friendly way for players (themselves sometimes hobbyist developers) to support each other, even if modestly. By the early 1990s, however, shareware had spawned its own big business wing, with enterprising companies that assisted with payment collection (adding conveniences such as toll-free ordering by phone), large-scale floppy diskette duplication, and postal exchange. The two most prominent of these full-service shareware publishers were Apogee Software and Epic MegaGames. Initially each company simply extended the reach of its founders' own games: Scott Miller

of Apogee's *Kingdom of Kroz* (1987) and Tim Sweeney of Epic's *ZZT* (1991). But as they began ramping up their publishing operations, Apogee and Epic established a regimented distribution framework far more organized than those of solo developers. Apogee released popular side-scrolling platform games, including *Duke Nukem* (1991), developed in-house, and *Commander Keen* (1990) from Id Software, an up-and-coming shareware developer founded by four friends from Texas and a client of Apogee's distribution services that would go on to create the blockbusters *DOOM* (1993) and *Quake* (1996). Epic countered with the *Jill of the Jungle* series in 1992.

But one game published by Apogee in May 1992 changed shareware—and the entire game industry—forever. *Wolfenstein 3D*, Id Software's World War II-themed, Nazi-hunting, verging-on-camp breakthrough that single-handedly popularized modern three-dimensional gaming and helped establish the first-person shooter (FPS) genre that has been a staple ever since. With the shareware model thrust into the limelight by *Wolfenstein 3D* and its successor *DOOM*, 1994 was a bumper year; Epic released a string of home console-style action titles: *Jazz Jackrabbit*, by Dutch graphics programmer Arjan Brussee, made PC side scrollers respectable, and *One Must Fall: 2097* did the same for 2-D fighting games. Apogee followed a similar tack with the vertical shoot-'em-up (or "shmup") *Raptor: Call of the Shadows*.

Tellingly, these games were predominantly published—rather than developed—by Epic and Apogee. That such middlemen companies could not only support themselves but indeed thrive through the shareware model signaled a

continuing loss of meaningful distinction between shareware and the mainstream commercial games industry. These publishers themselves drifted from their shareware associations and became fully integrated into the larger industry. Apogee changed its brand name to 3D Realms in 1996 and subsequently developed the successful *Max Payne* series (2001–3), and Epic is responsible for the *Unreal* series (1998–present) and 3-D technology engine. As home internet access rapidly increased in the mid-1990s, commercial game companies began offering extensive demos of upcoming or newly released games, a free source of entertainment that drew attention and viability away from the remaining shareware developers who had not already gone to larger distribution houses. By the final years of the decade, the shareware model had fallen from favor.

The shareware era of the 1980s and 1990s was neither the beginning nor the end of games produced and distributed by individuals. Strains of the shareware method have reemerged in recent years, with the establishment of the indie gaming community on PCs and the internet and the prevalence of the "free demo" and "try before you buy" model on Apple's App Store for the iPhone. Yet, although *shareware* originated as a descriptive term that defined a distribution and business model, it has become an associative one, attached to the specific cultural and historical situation of 1980s and 1990s home computing. For many curious users, shareware and freeware were their first chance to find and play video games—commercial or otherwise—on the new personal computers, and the form was a significant (and often underappreciated) force in the growth

and “mainstreaming” of game development, playing habits, and culture.

Shaw, Carol (1955–)

Carol Shaw is an early video game designer known for her work at both Atari and Activision. She started early, first programming in BASIC in a high school math class, then pursuing studies at UC Berkeley in electrical engineering and computer science at the undergraduate level, including a master’s in computer science.

Shaw joined Atari in 1978 as a micro-processor software engineer and immediately designed two games for the Atari 2600: a Polo game for Ralph Lauren Polo cologne and *3-D Tic-Tac-Toe* (1978). Although *Polo* was initially not released, the Strong National Museum of Play credits this game as the first documented game designed and programmed by a woman. *Polo* was eventually released in the 1996 CD-ROM compilation *Stella Gets a New Brain*.

Shaw continued her work at Atari, including *Othello* (1978), codesigned with Ed Logg; *Video Checkers* (1980); and *Super Breakout* (1981), codesigned with Nick Taylor. She also cowrote the *Atari BASIC Reference Manual* (1980) with Keith Brewster. In addition to

being a designer and programmer, Shaw, like many designers working at the time, did her own graphic design. In an interview, Shaw explained, “Nobody had developed any sort of thing to do [graphics] on the computer, so you’d just draw your thing on graph paper and then hand code it into the right hex values. I guess I would hand write my code [on paper] and then type it in and because we didn’t have screen editors that would edit the text at that point, we just had line editors—those fairly tedious things” (qtd. in Edwards 2011). At Atari, Shaw was known among her peers as a gifted programmer, particularly for her work on kernels for a number of 2600 games for which she was not the credited designer.

Shaw left Atari in 1980 for a stint at Tandem Computers before joining Activision in 1982. Activision’s founders had left Atari largely over frustration that developers did not benefit financially from their successful games, and so at the time, Activision had a very different structure for credit and royalties. Shaw’s first game at Activision, *River Raid* (1982) for the Atari 2600, is probably her most commercially successful and best-known title. Later, she worked on ports of *River Raid* for other systems and designed and programmed the game *Happy Trails* (1983) for the Mattel Intellivision. She then returned to Tandem in 1984 and stayed there for the rest of her professional career. Shaw retired early in 1990, a decision she says the financial success of *River Raid* enabled.

In 2017, the Game Awards recognized Shaw with the Industry Icon Award.

Shooting Games

One of the most common types of video games, shooting games, often colloquially called "shooters," are games in which the

main objective of the game involves shooting, the act of which usually requires either aiming, timing, or both, sometimes repeatedly in quick succession. Shooting games can further be defined by the player's point of view or perspective, the avatar's movement restrictions, ammunition restrictions, whether opponents can return fire, what you are shooting at, and how the shooting occurs. As shooting games evolve, additional features and considerations continue to be added.

THE PLAYER'S PERSPECTIVE

Shooting games are most commonly categorized by the player's perspective of the game's action, which is typically either a third-person perspective or a first-person

A player in Japan playing *Police 911*, an arcade game in which players use a light gun. (Courtesy of gwaar)

perspective. Earlier games were typically third-person perspective because a first-person perspective requires a three-dimensional setting that needs more computational power to achieve.

In third-person perspective games, the player's avatar is visible on-screen and can be seen shooting and getting shot. The avatar can be a player character that shoots (as in *Gun Fight* [1975]) or a vehicle with the capability to shoot, such as a tank, boat, airplane, or spaceship (as in *Combat* [1977], *Air-Sea Battle* [1977], and *Space Duel* [1982]), or crosshairs used as a gunsight that the player moves about the screen (as in *Missile Command* [1980]). Third-person shooting games can be further divided according to the on-screen arrangement of the player's avatar and enemies; vertical shooters limit the movement of the player's avatar to the bottom of the screen and allow the avatar to shoot upward (e.g., *Space Invaders* [1978] and *Centipede* [1980]), whereas side-scrolling shooters typically base their action horizontally (e.g., *Defender* [1980] and *Sea Dragon* [1982]). Other games allow free movement all over the screen and shooting in multiple directions (e.g., *Berserk* [1980] and *Robotron 2084* [1982]).

In first-person perspective shooting games (also known as first-person shooters [FPSs]), the perspective is from the avatar's point of view. The avatar is therefore not present on-screen, although a hand or weapon may extend into view from the bottom of the screen. The first-person point of view may be fixed, as in most shooting gallery games, or in motion, as in games such as *Battlezone* (1980) or *DOOM* (1993). Games with moving first-person perspectives may also require the player to watch for

attacks coming from behind and may provide radar scopes or other such devices that allow the player to monitor enemies in off-screen space. Since their earliest incarnations (i.e., *Maze War* [1974] and *Battlezone* [1980]), first-person shooting games have evolved into a large subgenre with a wide variety of examples, ranging from single-player games, to multiplayer games, to massively multiplayer online role-playing games (MMORPGs), and many games in other genres that feature shooting capabilities, even if they are not the focus of the game, contain situations not unlike first-person shooting games. FPSs have also been studied from the point of view of phenomenology.

One type of shooting game arguably falls between first-person and third-person shooting games. These games involve the use of a light gun or other kind of gun-shaped peripheral device that allows the player to shoot directly at objects on-screen, such as *Qwak!* (1974), *Bullet Mark* (1975), and *Outlaw* (1976). Because the player may look along the length of the gun to aim, such games are similar to first-person shooting games, yet the graphics in some of these games remain relatively flat and may have more in common with the graphics of third-person shooting games. A similar effect occurs in such games as *Missile Command* (1980), in which the player moves the crosshairs of a gunsight around on-screen and fires when it is placed over targets.

CHALLENGES AND SKILLS

Shooting games can be designed to pose different challenges that test a variety of skills. First, there is the nature of the shooting mechanisms used; weapons

may be used to fire bullets, missiles, grenades, laser bolts, a variety of other projectiles, or even other things, such as the holes that the player uses to connect spaces in *Portal* (2007). Some games will limit the speed at which shots can be fired; for example, after firing, a player may have to wait before the shot leaves the screen or hits something before another shot can be fired. Other games may limit the amount of ammunition a player has or, in a two-player game, provide each player with the same amount of ammunition (as in the Atari VCS 2600 version of *Outlaw* [1976]).

Aiming is one of the skills most often required and may be done through the positioning of a weapon (as in *Space Invaders* [1978] and *DOOM* [1993] or the direct position of a gunsight or crosshairs (as in *Missile Command* [1980] and *Star Wars* [1983]). Some games may also provide the player with a choice of weapons, each with different capabilities, and require the player to choose between them and change from one to the other as the game progresses (as in *Halo: Combat Evolved* [2001]).

Timing is almost always required as well and is needed for shooting enemies and targets that appear and disappear or those that are moving, which requires the player to compensate for his or her distance and speed of movement. Timing also includes shooting things quickly, especially when returning fire, and shooting things in the right order, with threat assessment determining which targets need to be fired on first. In games in which weapons need to be reloaded, reload time may need to be worked into the timing of the game.

Other skills include the careful use of limited resources (such as ammunition

that runs out or batteries that need recharging), knowing when to use different types of ammunition or weaponry, and avoiding shooting at things or characters that should not be fired on (such as civilians or assets that a player needs). Players will frequently need to choose between shooting and other activities, such as evasion, the finding of objects (including additional ammunition), the healing of wounds, and interactions with other players and game characters.

HISTORY

Shooting games can be traced back to their military roots and, commercially, to shooting galleries and electromechanical games, such as *Automatic Shooting Range* (1895), *Target Practice* (1922), *Sharpshooter* (1935), *Safari Gun* (1954), and *Apollo Moon Shot Rifle* (1969). From their earliest conception in the late 1940s, video games have typically included shooting as an activity (see Patent #2,455,992), so it is not surprising that the first video game, *Spacewar!* (1962), was a third-person shooting game, as were the first two commercial video games, *Galaxy Game* (1971) and *Computer Space* (1971), which were both versions of *Spacewar!* The first shooting games to feature a first-person perspective were the mainframe games *Maze War* (1974) and *Spasim* (1974), and the first commercial FPS was *Battlezone* (1980).

The 1970s saw the release of such arcade games as *Tank!* (1974) (similar to certain mainframe games, such as *Panther* [1975]) and *Space Invaders* (1978) and numerous home video games that used “player-missile graphics” programming designed with shooting games in mind. Shooting games rose in popularity and

number, and by the decade's end, they had surpassed ball-and-paddle games as the dominant type of video game.

With the rise of three-dimensional graphics during the 1980s and 1990s, first-person shooting games grew alongside third-person shooting games, and each developed into dozens of variations, with such features as limited ammunition, different types of weaponry, and games specifically designed to test different skills, such as aiming, timing, precision, strategy, and quick decision making. Although most games were representational to some degree, other shooting games were abstract in design, such as *Tempest* (1981). Games that introduced new technology to players, such as the virtual reality (VR) game *Dactyl Nightmare* (1992), which used a head-mounted display, were often shooting games so that their gameplay would be intuitive and familiar to players, even when their hardware was not.

Other technologies of the 1980s and 1990s, such as improved graphics, faster CPU speeds, and more sophisticated gameplay mechanics, helped boost the popularity of the genre, whereas networked games and other online games, and eventually MMORPGs, meant larger groups could play together, providing more intelligent opponents than the artificial intelligence (AI) that the games of that time could provide. Companies such as Id Software, producers of the *DOOM* and *Quake* series, specialized in shooting games and helped bring the genre to maturity during the 1990s (Rehak 2007).

By 2000, shooting games and their various subgenres had well-established conventions as well as technologies that could heighten the gameplay experience, including peripherals especially designed

for shooting games. One such device, the 3rd Space Gaming Vest by TN Games, uses force-feedback technology to physically simulate the impact of bullet hits, grenade blasts, and other events to the player's torso. The vest uses eight pneumatic air pockets that inflate and deflate in various places around the player's chest and back to simulate directional impacts. Now that 3-D televisions and VR systems are available, 3-D shooting games will be made for them.

The great diversity and popularity of shooting games makes the genre one of the most widespread and growing, and to some extent, the shooting game genre is perhaps the one used most often to represent video games in the mind of the general public, for better or for worse.

Sierra Entertainment

Sierra Entertainment (formerly known as Sierra On-Line) was one of the earliest publishers of home computer games and one of the biggest game companies of the 1980s and 1990s. It was initially known primarily for its graphic adventure games, such as *King's Quest* (1984), but eventually branched out into many other

kinds of games. After a series of mergers and acquisitions, the company shed all of its development studios and effectively became a defunct brand by 2008.

The history of Sierra On-Line can effectively be divided into three eras: the period when it was owned and run by its founders, Ken and Roberta Williams; the period in the late 1990s when it was no longer independent but still a major publisher of a wide diversity of games; and, finally, the period of deterioration and effective dissolution in the years following 2000.

Ken Williams founded On-Line Systems in 1979 to create software for business applications. His spouse, Roberta, convinced him to try releasing computer games instead, and in 1980, they released *Mystery House* for the Apple II, a game that is often described as the first home computer-based adventure game with graphics. The couple quickly followed with other titles and swiftly became a major force in the fledgling computer game industry. They moved to Oakhurst, California, near the Sierra Mountains and Yosemite National Park, and changed the company name to Sierra On-Line in 1982 to avoid confusion with another company of the same name.

Sierra created a fairly diverse set of offerings, making its own games, publishing titles developed by other companies (e.g., Sydney Development's *BC's Quest for Tires* in 1983), and porting the popular arcade game *Frogger* to home computer systems such as the Atari 400 (1981) and IBM PC (1983). For a brief time, Sierra even entered the console game market, but it exclusively focused on home computer games after losing money in the video game market crash of 1983. Sierra primarily built its reputation

on its significant range of graphic adventure game series. Its Hi-Res Adventure series, including *Mystery House* and *The Wizard and the Princess* (1980), generated significant profits, and in the mid-1980s, the company established a string of hits in the genre. Roberta Williams's own *King's Quest*, released in 1984, was the most well-known and longest-running game—the series eventually included eight titles, the last of which was released in 1998. Other popular series included the *Space Quest* games by Mark Crowe and Scott Murphy, the *Leisure Suit Larry* series by Al Lowe, the *Police Quest* games, Lori and Corey Cole's *Quest for Glory* series, and Jane Jensen's *Gabriel Knight* games.

In the early to mid-1990s, Sierra embarked on a series of acquisitions of other developers. Two of these were particularly notable. The first was Dynamix in 1990. This studio produced several popular Sierra titles, including flight simulators such as *Red Baron* (1990), family-oriented titles such as the puzzle game *The Incredible Machine* (1992), vehicle combat simulators such as the *Earthsiege* games, and the first-person shooter *Tribes* titles. In 1995, Sierra acquired Impressions Games, which released many popular strategy series, such as *Lords of the Realm* (1994) and the *City Building* series, including titles such as *Caesar III* (1998) and *Pharaoh* (1999).

Sierra was an early pioneer in online gaming. In 1991, it launched the Sierra Network, which was dedicated to game-playing via modems. Although early offerings were mostly board game remakes, the company introduced *The Shadow of Yserbius* in 1992, which makes it one of the earliest graphical multiplayer online role-playing games. In

mid-1993, AT&T bought a 50 percent stake in the network and renamed it the ImagiNation Network. AT&T purchased the rest of the network in 1995. Sierra then went on to publish *The Realm Online* (1996), one of the earliest internet-based massively multiplayer on-line role-playing games (MMORPGs). In 1999, the game was sold to Codemasters.

By the mid-1990s, Sierra was a giant in the games industry. Consumer-marketing corporation CUC International, looking to expand into software development, purchased Sierra and educational software company Davidson & Associates (which owned developer Blizzard Entertainment) for nearly \$2 billion in shares in 1996. Ken Williams stepped down as CEO of Sierra and by 1998 had retired. In late 1997, CUC in turn merged with HFS, a company primarily known for hotel chains and real estate, to form Cendant. Only a few months after the creation of this new entity, Cendant revealed that its executives had engaged in significant accounting fraud, sending the corporation's stock value into the tank. In the fall of 1998, Cendant sold its entire software division, along with Sierra, to Vivendi.

During this period of corporate tumult, Sierra continued to score successes as a publisher. In 1997, after acquiring Berkeley Systems, Sierra released multiple editions of the quiz game *You Don't Know Jack*. In 1998, it published Valve's hit *Half-Life* and continued this relationship until Valve successfully sued Vivendi for unauthorized distribution of software to cyber cafés, a lawsuit initiated in 2002 and concluded in 2005. However, despite these strong ventures, Sierra was failing to produce sufficient profits for Vivendi. In February

1999, the company laid off many employees and shut down several developers, including Sierra's historic Yosemite studio in Oakhurst, California.

By this time, Sierra no longer had much of a connection to its past and effectively functioned as an administrative division of Vivendi. It continued to lose money, and when Vivendi, facing significant financial pressure, sold its games unit to Activision in the summer of 2008, the newly formed Activision Blizzard, Inc., effectively—although without announcement—retired Sierra, merging all its operations into other parts of the corporation. In 2014, however, Activision revived the brand for publishing indie titles, including a reboot of the *King's Quest* series released in several episodes throughout 2015 and 2016.

Sierra developed or published some of the most well-known and profitable games of the 1980s and 1990s, and many prominent game makers started their careers or spent part of them with the company. In addition to the adventure game makers previously discussed, the list includes Richard Garriott, who published *Ultima II* with Sierra in 1982; Jeff Tunnell, who founded Dynamix and is credited in dozens of games, including *Starsiege* (1998) and *Tribes 2* (2001); and David Kaemmer, who has created multiple racing simulators, including *NASCAR Racing* (1994) and iRacing.com.

Silent Film

Silent film has been an essential source of inspiration for game design, both consciously and unconsciously, nourishing the video game medium with the visual freedom, the attractational quality, and the kinetic wonders of early cinema. A close study of the aesthetics and forms of silent film can help video game developers in their creative choices, as in the case of designer Warren Spector and titles such as *The Misadventures of P. B. Winterbottom* (2010), revealing at the same time a history of hidden influences between both media, from Buster Keaton's slapstick to the universe of *Super Mario Bros.* (1985) and from the action-adventure sequences of *The Thief of Bagdad* (1924) to the gameplay of *Prince of Persia* (1989).

The images of early cinema shared a number of stylistic patterns with the first video games. The absence of synchronized dialogue and the supremacy of visual attractions pushed creators—both early filmmakers and game designers—toward truly imaginative ways of relating the moving image to its audiences. Researchers such as Tom Gunning and

Henry Jenkins have studied how playfulness, spectacle, and sight transformation bridged the practices of film with those of magic, circus, music hall, and vaudeville, just as arcades merged with other forms of public entertainment and body performance. As Mark J. P. Wolf (2003) has noted, the visual freedom of early video games opened the path for a certain abstract-motion expression, concerned with gameplay visuality and not necessarily sacrificed to verbal storytelling, a path shared by cinema during its first decades. Such coexistence of images without words, movements without plots, and attractions without boundaries questions our assumptions about film and game culture, proving that the richness, multiplicity, and differential nature of both media goes way beyond the restrictions of allegedly cinematic techniques, such as cutscenes, verbal dialogue, and hyperrealism (that make games look more like talkies but not necessarily like films).

Visually enclosed by what Noël Burch called the "autarchy of tableau," Méliès and Pathé Frères fantasy reels shared with early games an aesthetic awareness of the frame. Acts of gameplay were literally portrayed, as we can see when the children of *Le théâtre électrique de Bob* (1906) connect a couple of electrical marionettes and start a screen fight like the ones in *Street Fighter* (1987) and *Mortal Kombat* (1992). Within the determined, magical space of the frame, a path was open for visually stunning effects and changes in shape, form, and motion. Humans became geometrical figures like the ones in *Les Kiriki, Acrobates Japonais* (1907), game pieces whose movements and combinations resemble the legendary gameplay of *Tetris* (1985).

Early mischief gags in comedy reels such as *Pickpock ne Craint pas les Entraves* (1909) soon started to work around chases, jumps, and visual transformations, perfecting a system of vertical and horizontal interplay between the main character, his antagonists, and the surrounding space. Connecting floors (*Pac-Man* [1980]), stairs (*Donkey Kong* [1981]), passageways (*Bubble Bobble* [1986]), and magic vehicles (*Paperboy* [1984]) engaged a certain development in early film montage before they became conventions of video game history.

The discoveries of early film were gradually reinterpreted and systematized, crystallizing throughout the silent masterpieces of the 1920s. In the realm of slapstick, the stunts, jumps, and chases of Mack Sennett's Keystone Kops were refined in the creations of Charles Chaplin, Buster Keaton, Harold Lloyd, Larry Semon, and other silent clowns, just like the primitive moves of *Jumpman* (1983) evolved through the platforms of *Super Mario Bros.* (1985). Among those masters of the gag, Keaton was probably the one who brought his obsession with motion, interfaces, and Rube Goldberg machines to a higher degree of visual lucidity (sublimating Henri Bergson's mechanics of laughter).

The development of sight gags—based on the creation, repetition, and variation of a kinetic pattern through time—resembles the way game designers conceive certain interactions between a moving figure and the surrounding spaces. As in the early *Super Mario* and *Sonic* sagas, slapstick reels captured a screen trajectory by reconstructing the trace of a character's action (jump, chase, pie in the face) and its physical interactions (platform, rotor, slide, cliff,

pendulum, pulley, seesaw, zip line, lever). Classic sequences of the silent era, such as the final chase of *Seven Chances* (1925) and the dream sequence of *Sherlock Jr.* (1924), can be regarded as creative tools for designing imaginative gameplay, while connecting with the glitches and silent ruptures of Samuel Beckett's *Film* (1965) and the playful sensibility of contemporary game shows, such as Takeshi Kitano's *Takeshi's Castle* (1986). A kind of absurd playable humor that resurfaces in games that limit the player's bodily performance on purpose, such as *QWOP* (2010) or *Octodad* (2014), foster a series of contingent visual gags frequently shared online as machinima.

The echoes multiply if we compare the canon of Hollywood's silent adventure genre with its equivalents among early video games. The jumps and stunts of Douglas Fairbanks in *The Mark of Zorro* (1920) bring to mind the hanging vines of *Pitfall!* (1982) and *Jumpman* (1983), just like the climbing and sliding between walls and ladders evoke the levels of *Mega Man* (1987). Distinctive action sequences, such as Fairbanks running through the drawbridge in *Robin Hood* (1922), foreshadow memorable moments in games such as *Castlevania* (1986) and *Kid Icarus* (1986), and the final boss structure in the caves of *Metroid* (1986) is literally contained in the catacombs of *The Thief of Bagdad* (1924). Aside from the recurrence of visual motifs, silent film shared with the first video games the use—and triumph—of printed title cards. In the early years, both media shared the necessity of narrating without synchronized dialogue, a technical requirement that encouraged the creation of memorable visual texts: from the revenge island in *The Black Pirate* (1926) to the revenge

parody in *Monkey Island 2* (1991), not to mention the unforgettable title cards of *The Legend of Zelda* (1986), a saga that still relies on the wonder of silent words.

These hidden influences are finally amplified by the conscious inspiration on silent film that certain game designers have proved and vindicated. Warren Spector, trained as a film critic before becoming the creator of *Deus Ex* (2000), has publicly praised the imaginative powers of early film to inspire compelling video games, from his evocations of David W. Griffith to the cartoon gameplay of *Epic Mickey* (2010). Even more, silent film aesthetics literally merge with gaming in games such as *The Misadventures of P. B. Winterbottom* (2010), a work that embraces—and turns into specific, brilliant gameplay—sequences from silent milestones such as *Le Voyage dans la Lune* (1902), *Safety Last* (1923), and *Metropolis* (1927), not to mention the minimalist black-and-white sensibility of *Limbo* (2010) and *Inside* (2016), where the Kafkaesque monochrome tone goes back to the silent classics of Dreyer and Murnau. Because, after all, as long as game designers such as Fumito Ueda or Jenova Chen rely on the expressivity of bodies traversing landscapes, without the help or hindrance of words, silent cinema will never cease to come back to life under the mask of new video games.

Silicon Knights v. Epic Games

The ownership of a game’s code and the legal implications of *mods* (modifications made by others) were called into question in the court case *Silicon Knights v. Epic Games*, making it a case with wide-ranging significance. While working on

the game *Too Human* (2008) for Nintendo, the Canadian company Silicon Knights used Epic Games' Unreal Engine 3 to create the game. When the game did not sell well, lead game designer Denis Dyack complained that the game engine was flawed, blaming Epic Games. Silicon Knights then sued Epic Games, demanding licensee support, which would include engine-specific upgrades and updates; Epic had upgraded the Unreal Engine for its own game, *Gears of War* (2006), and Silicon Knights wanted access to the upgraded code, claiming the original code was unworkable.

Epic Games refused to give access to the code and counterclaimed that Silicon Knights had infringed Epic's copyrights and misappropriated trade secrets. Epic accused Silicon Knights of copying proprietary code from the Unreal Engine, removing copyright claims and developer comments within the code.

In May 2012, the decision was granted in favor of Epic Games, requiring Silicon Knights to pay \$4.45 million in damages and another \$4.678 million for attorney fees. In November of that year, Silicon Knights was also ordered to destroy the engine it had developed for *Too Human* and to remove all copies of *Too Human* as well as the game *X-Men: Destiny* (2011) and three unreleased that were underway at the time, all of which used the copyright-infringing engine. Later, in January of 2014, a new post-trial ruling raised Epic's award to \$9.2 million.

The loss of the court case ruined Silicon Knights financially, leading to layoffs and the company's filing for bankruptcy. The result of the case is also that precedent has been set regarding the rights of "mods" that include any proprietary code

or any other uses of game code other than by the owners of that code.

Sim Series

The *Sim* series is a successful franchise of simulation games created by designer Will Wright and Maxis Software that was subsequently taken over by major games publisher and developer Electronic Arts (EA). Rather than immersing players directly in first- or third-person gameplay directed toward a linear mission-based structure, the series is credited with pioneering the "god game" genre, which allows players to oversee the creation and maintenance of a larger simulated system from a somewhat removed godlike vantage point. Although the scenarios that inform each *Sim* title

vary considerably, most of the series' games have in common their rejection of fantasy settings in favor of scenarios with origins in the real world, which players may, in many cases, relate to their everyday lives.

The *Sim* series launched in 1989 with the release of *SimCity*, an urban planning simulator that allows players to design, develop, and maintain their own cities. In contrast to training-based computer simulators with their origins in the military, which approximated the experience of flying or driving, *SimCity* was one of the first computer games to perform the type of simulation that dynamically models an entire system. Along with roughly contemporaneous simulation games, such as *Populous* (Peter Molyneux, 1989) and *Civilization* (Sid Meier, 1990), *SimCity* would revolutionize the game experience and industry by helping popularize the new genre of god games and laying an enduring foundation for the rest of the *Sims* series to build on. Rather than adhering to the quest structure most common to video games at the time and placing the player in control of an individual player character, *SimCity* put players in charge of an entire population whose development and well-being depended on the player's strategic decisions. It also featured an isometric perspective that introduced a new way of looking at gameplay—that of the third-person total overview of an expansive landscape, the scale of which gave the “godlike” impression of observing a vast game world in its entirety.

Both of these innovations made the player feel, quite literally, like a god in the game world. “Mayor” players are presented with an empty landscape that they must clear, plan, and develop

according to a range of competing economic, political, and human factors. Players spend their mayoral budget installing power plants and police stations; subdividing residential, commercial, and industrial zones; and creating transportation networks using the editing toolbar that partially frames their God's-eye view. If enough Sim-citizens like the city the player has built, the population thrives, and so do tax dollars for further development; if they do not like the city, the budget runs dry, and the mayor loses his or her office—in other words, the system, and thus the entire simulation, will fail.

In the wake of its unanticipated success, *SimCity* produced multiple expansion packs and sequels, including *SimCity 2000* (1994), *SimCity 3000* (1999), *SimCity 4* (2003), and *SimCity Social* (2012). Each of these subsequent games takes advantage of the increased processing power of the hardware on which they are played, for example, by offering enriched graphics, more editing tools, and the enhanced ability to zoom in and out of the simulation so that cities may be examined as closely as street level. However, the games' fans and critics alike have suggested that for all that the visual experience of *SimCity* has changed in later iterations, the nature of its gameplay remains quite faithful to that laid out in its original version.

In addition to achieving critical acclaim and unexpected commercial success, *SimCity* was one of the first computer games to be put to use in education, and by the early 1990s, it had been adopted in more than ten thousand schools in the United States alone to teach everything from urban planning to geography. However, it has also been

argued that the educational value of *SimCity* is not found in how it teaches players simulated skills that they can then apply in the real world, but rather in how it teaches players to think like the computer running the simulation. Ted Friedman (1999) suggests that god games like *SimCity* teach users to internalize the logic of the computer program; to win, you must figure out the rules of the game, predict consequences, and anticipate the computer's responses until your decisions become as smoothly mechanized and intuitive as those of the computer—which, he suggests, is one of the true pleasures of this type of gaming experience.

SimCity's success prompted Maxis to create a wide range of *Sim* spin-offs, allowing players to simulate everything from the minutia of an ant colony (*SimAnt* [1991]) to the expansiveness of an entire planet (*SimEarth* [1990]), with every degree of scope and complexity in between. The diversity of *Sim* spin-offs is evident in their titles, which include *SimFarm* (1993), *SimTower* (1994), *SimIsle* (1995), *SimTown* (1995), *SimGolf* (1995), *SimCopter* (1996), *SimTunes* (1996), *SimPark* (1996), *Streets of SimCity* (1997), and *SimSafari* (1998). These latter spin-offs generally proved less commercially and critically successful than the *SimCity* games, and, indeed, the lukewarm sales and reception of most of these titles were believed to have factored into Maxis's 1997 sale to EA. However, there was one notable exception to the lackluster performance of non-*SimCity* spin-offs: *The Sims* (2000), a “virtual dollhouse” (in designer Wright's words) that allows users to create and manage the lives of a family of simulated people, or “Sims.”

EA was initially reluctant to release *The Sims* because of its seemingly

mundane premise and finally did so with minimal fanfare or promotion. Despite this, *The Sims* quickly became one of the best-selling computer games of all time, spawning multiple expansion packs and sequels, including *The Sims Online* (2002), *The Sims 2* (2004), *The Sims 3* (2009), *The Sims Medieval* (2011), *The Sims Social* (2011), and *The Sims 4* (2014). As with *SimCity*, these later titles have been viewed as innovating the visual aspects of the original game and the degree to which users may customize their Sims and surroundings rather than departing from the original in terms of gameplay. The one sequel that did drastically alter the single-player, off-line format of the *Sims* games—the massively multiplayer online role-playing game (MMORPG) *The Sims Online*—was considered a costly disappointment. (Subsequently rebranded as *EA-Land*, it was shut down and taken off-line in 2007.) Some of the most recent *Sims* and *SimCity* spin-offs, meanwhile, such as *SimCity Societies* (2007) and *MySims* (2007) for the Nintendo Wii and Nintendo DS, combine certain elements of *SimCity* and *Sims* gameplay by allowing players to manage both their Sims and their larger urban environment.

Within the *Sim* series, *The Sims* games in particular have been credited with attracting a more diverse demographic of players—especially female players—to video games. *The Sims*' success in broadening gamer demographics has been attributed to the ways in which it deviates from the predominantly masculine gender positioning of video games, creating a game world where crucial decisions revolve around human relationships and the management of domestic space rather than weapon selection or fantastical feats

of strength. Players create and customize their Sims in terms of appearance and personality traits and build, customize, and furnish their home environments to help meet (or, in some cases, thwart) their various needs. Sims respond to player input, but they are not wholly avatars that do the player's bidding. They are also directed by artificial intelligence (AI), creating responses and situations that are semiautonomous of the player's control. Just as the mayor of *SimCity* must balance the competing demands of an urban environment, players must juggle the human needs of their Sims, ensuring they receive adequate food, sleep, socialization, employment, and shelter, right down to such minutia as properly timed bathroom breaks. Although players quickly become engrossed in these tasks, some complain that their mundane realism makes them feel like an "underpaid virtual housemaid," in Gonzalo Frasca's (2001) words.

The Sims and its sequels are ostensibly open-ended; players do not work toward a preset endpoint but rather operate according to the broad goal of keeping their Sims content and alive. Because one of the easiest ways to make your Sims happy is to buy them what they want, the game's depiction of consumerism has been greatly debated. Although one side of the debate contends that the tongue-in-cheek nature of *The Sims* actually critiques or at least allows an exploration of excessive materialism (see, e.g., Herz 2000), the other side faults it as a kind of yuppie-training simulator that suggests success is equated with acquiring more and better objects (Kline et al. 2003).

Creator Will Wright has described the *Sim* series as being more "software toys" than actual games because of their

open-endedness and lack of a clearly goal-oriented structure. Unlike titles that lead players toward a singular experience of winning or beating the game, the *Sim* games ostensibly allow players to set their own goals and decide for themselves when they have achieved them. This permits players to engage in a variety of play styles and produce a wide range of possible outcomes within the simulated environment. For example, in the *SimCity* games, players may construct their ideal cities in a variety of ways, differently prioritizing such elements as industrial development, residential growth, and urban renewal (to name a few), thus producing a wide range of economic and social landscapes, or they may choose to construct their cities only to obliterate them with a tornado or tidal wave conjured by the games' assorted disaster modes. Similarly, the virtual dollhouse format of *The Sims* games means that players may pursue the more obvious objective of meeting their Sims' needs with a wide variety of consumer purchases and basic life maintenance tasks; however, they may also choose to neglect their Sims' needs and torture them in a variety of ways.

Wright has suggested that his overarching goal for the series was to create game worlds that provide as big a "solution space" as possible, wherein no two players may problem solve in exactly the same way, suggesting the possibility of seemingly infinite solutions and, thus, a gaming experience unique to the player (Pearce 2002). On these grounds, the series has been praised for its success in creating "emergence"—complex, varied results in gameplay emerging out of seemingly simple interactions. Although there are still limits to this emergence

enforced by the design and technical constraints of the game software, the *Sim* series has been widely credited as one of the most successful examples of emergent gameplay in video game history.

The *Sim* series has also been cited as evidence that video games can lack any discernible narrative or story, a view commonly espoused by game scholars associated, for a time, with the ludology movement within game studies and its advocacy for studying games as games, not stories. However, the counterargument has been made by Wright himself that the *Sim* games can actually function as a kind of authoring tool in which players can produce their own uniquely personal narratives through their interaction with the simulation. Henry Jenkins (2004) terms these types of narratives “emergent” because they are not pre-structured but rather take shape through gameplay specific to the individual player. Players can then share these narratives with the active online community Maxis has cultivated for further engagement with and interest in the franchise—for example, by posting user-created scrapbooks or virtual novels about their *Sim* characters, storyboards, and urban design plans.

EA acquired the franchise rights to the *Sim* series in 1997 when it acquired Maxis. Wright and Maxis initially maintained a lead development role in the series; however, more recent titles (such as *SimCity Societies*, the *MySims* series, and *The Sims 3*) have been developed and published without the direct involvement of Wright or Maxis, with EA either developing new *Sims* projects internally or tasking them to other external developers. The highly popular *Sims* franchise, for example, is now fully under the

purview of EA’s in-house Sims Studio. The company also released *SimCity* (2013), a reboot of the series; the mobile game *SimCity BuildIt* (2014); and *The Sims Mobile* (2014).

Over its long life span, the *Sim* series has diversified from being played solely on computers to being ported across a wide range of console platforms, including the most recent generation of systems (i.e., the Microsoft Xbox 360, the Nintendo Wii, and the Sony PlayStation 3).

Sims, The Series

The Sims is a series of sandbox/social simulation games created by star designer Will Wright and published by Maxis and Electronic Arts (EA). Players interact with a virtual dollhouse, building and decorating homes and (in later games) other locations for virtual people called Sims. Sims can form relationships, raise

families, and progress in various careers, and while there are quests and goals in some versions of the game, play is for the most part open and unending. The Sims have needs that must be met for them to be happy and able to follow player commands. In the original *The Sims* (2000), the needs were hunger, hygiene, bladder, energy, social, and fun. Later versions of the game made minor modifications to these motives affecting Sim moods. In *Sims 4* (2013), *hunger* was replaced by *thirst* for vampire Sims, for example. The Sims speak a made-up language called Simlish and use Simoleons (an in-game currency) to buy and sell items. The majority of *The Sims* games and related content releases are rated T (Teen) by the ESRB, with a handful rated E (Everyone).

Will Wright has cited Activision's *Little Computer People* (1985) as one of his inspirations for creating *The Sims*. Other precursors include Activision's *Alter Ego* (1986), Wright's own *SimCity* series (1989) and *SimAnt* (1991), and Mindscape's *Creatures* (1991). The series is sometimes compared to the Learning Company's *Babyz* (1995), Nintendo's *Animal Crossing* series (2001–17) and *Tomodachi Life* (2013), and Linden Labs' *Second Life* (2003–present).

According to Cory Ondrejka, “The Sims was the first mass-market game to heavily utilize player created content,” and EA claims that over 80 percent of available Sims content was user created (Ondrejka 2013, 84). Allowing players to design and share their own game content increases player engagement with the games and extends gameplay possibilities by providing a continual source of new game content at no cost to Maxis. *The Sims Resource* (TSR) is a fansite that was started in 1999 that is dedicated to offering custom content for download (some free, some not). Players design and upload their own designs for all types of items in all four *Sims* games: character designs, skin tones, hair, makeup, and clothing; houses, furniture, floors, and walls; pet designs and clothing; and more. The site credits uploaders for their work using their chosen forum names. For example, “wtrshpdown” designed and uploaded a male and female version of a T-shirt bearing the Puerto Rican flag for Sims to wear in *Sims 4*. *The Sims Community* was founded by Jovan Jović and has no connection to Maxis or EA, but the site has news and articles about new *Sims* releases and player modifications. *The Sims Catalog* is a fansite

dedicated to custom content for *The Sims 4* and promises never to charge a fee for membership.

Creative play of *The Sims* is not limited to designing new game content. Starting with *The Sims*, players adapted the Family Album feature of *The Sims* to tell stories using their Sims. Though the designers intended the Family Album to function like a traditional photo album, storing snapshots of interesting moments in the Sims' lives, players realized that it could also be viewed as a comic book or storyboard. By carefully planning a series of snapshots, players could create simple stories and share them online. In *The Sims 3* (2009), a video camera function was added, allowing players to create in-game movies using their Sims. This coincided with the rise of the machinima phenomenon, and soon machinima productions using *The Sims* appeared. Notable examples include Thuyen Nguyen's *An Unfair War* (2006) and Rooster Teeth's *The Strangerhood* series (2004 and 2015).

The official *Sims* games are relatively uncontroversial, although user-made content lacks oversight and may contain offensive themes or images. *The Sims* games have allowed same-sex relationships between Sims since the first release, which was criticized by more conservative reviewers. In 2019, however, *The Sims 4* was criticized by players for *not* including a lesbian Pride flag along with other LGBTQ Pride objects added to the game on June 18, 2019, as part of its partnership with It Gets Better. The *Sims 4* originally came with a character trait called “insane” that caused the character to act in a random fashion, making the character harder for the player to

control. After protests from mental health and disability activists, EA changed the name of the trait to “erratic.”

LIST OF GAMES AND THEIR ANCILLARY RELEASES

The Sims (2000): Expansion packs: *The Sims: Livin’ Large* (2000), *The Sims: House Party* (2001), *The Sims: Hot Date* (2001), *The Sims: Vacation* (2002), *The Sims: Unleashed* (2002), *The Sims: Superstar* (2003), *The Sims: Makin’ Magic* (2003).

The Sims 2 (2004): Expansion packs: *The Sims 2: University* (2005), *The Sims 2: Nightlife* (2005), *The Sims 2: Open for Business* (2006), *The Sims 2: Pets* (2006), *The Sims 2: Seasons* (2007), *The Sims 2: Bon Voyage* (2007), *The Sims 2: FreeTime* (2008), *The Sims 2: Apartment Life* (2008).

Stuff packs: *The Sims 2: Happy Holiday! Pack* (2005), *The Sims 2: Family Fun Stuff* (2006), *The Sims 2: Glamour Life Stuff* (2006), *The Sims 2: Happy Holiday Stuff* (2006), *The Sims 2: Celebration! Stuff* (2007), *The Sims 2: H&M Fashion Stuff* (2007), *The Sims 2: Teen Style Stuff* (2007), *The Sims 2: Kitchen & Bath Interior Design Stuff* (2008), *The Sims 2: IKEA Home Stuff* (2008), *The Sims 2: Mansion & Garden Stuff* (2008).

The Sims 3 (2009): Expansion packs: *The Sims 3: World Adventures* (2009), *The Sims 3: Ambitions* (2010), *The Sims 3: Late Night* (2010), *The Sims 3: Generations* (2011), *The Sims 3: Pets* (2011), *The Sims 3: Showtime* (2012), *The Sims 3: Supernatural* (2012), *The Sims 3: Seasons* (2012), *The Sims 3: University Life* (2013), *The Sims 3: Island Paradise* (2013), *The Sims 3: Into the Future* (2013).

Stuff packs: *The Sims 3: High-End Loft Stuff* (2010), *The Sims 3: Fast Lane Stuff* (2010), *The Sims 3: Outdoor Living Stuff* (2011), *The Sims 3: Town Life Stuff* (2011), *The Sims 3: Master Suite Stuff* (2012), *The Sims 3: Katy Perry Sweet Treats* (2012), *The Sims 3: Diesel Stuff* (2012), *The Sims 3: 70s, 80s, & 90s* (2013), *The Sims 3: Movie Stuff* (2013).

Content available from the in-game store: *The Sims 3: Riverview* (2009), *The Sims 3: Barnacle Bay* (2010), *The Sims 3: Hidden Springs* (2011), *The Sims 3: Lunar Lakes* (2012), *The Sims 3: Lucky Palms* (2012), *The Sims 3: Sunlit Tides* (2012), *The Sims 3: Monte Vista* (2012), *The Sims 3: Aurora Skies* (2013), *The Sims 3: Dragon Valley* (2013), *The Sims 3: Midnight Hollow* (2013), *The Sims 3: Roaring Heights* (2013).

The Sims 4 (2013): Expansion packs: *The Sims 4: Get to Work* (2015), *The Sims 4: Get Together* (2015), *The Sims 4: City Living* (2016), *The Sims 4: Cats & Dogs* (2017), *The Sims 4: Seasons* (2018), *The Sims 4: Get Famous* (2018), *The Sims 4: Island Living* (2019).

Game Packs: *The Sims 4: Outdoor Retreat* (2015), *The Sims 4: Spa Day* (2015), *The Sims 4: Dine Out* (2016), *The Sims 4: Vampires* (2017), *The Sims 4: Parenthood* (2017), *The Sims 4: Jungle Adventure* (2018), *The Sims 4: StrangerVille* (2019), *The Sims 4: Realm of Magic* (not yet released).

Stuff packs: *The Sims 4: Luxury Party Stuff* (2015), *The Sims 4: Perfect Patio Stuff* (2015), *The Sims 4: Cool Kitchen Stuff* (2015), *The Sims 4: Spooky Stuff* (2015), *The Sims 4: Movie Hangout Stuff* (2016), *The Sims 4: Romantic Garden Stuff* (2016), *The Sims 4: Kids Room Stuff* (2016), *The Sims 4: Backyard Stuff* (2016), *The Sims 4: Vintage*

Glamour Stuff (2016), *The Sims 4: Bowling Night Stuff* (2017), *The Sims 4: Fitness Stuff* (2017), *The Sims 4: Toddler Stuff* (2017), *The Sims 4: Laundry Day Stuff* (2018), *The Sims 4: My First Pet Stuff* (2018), *The Sims 4: Moschino Stuff* (not yet released).

Other downloadable content: *The Sims 4: Rewards* (2014). Bonus Sims 4 content for owners of *The Sims 3: The Sims 4 Digital Deluxe Upgrade: Life of the Party* (2014), *The Sims 4 Digital Deluxe Upgrade: Awesome Animal Hats* (2014), *The Sims 4 Digital Deluxe Upgrade: Up All Night* (2017), *The Sims 4: Holiday Celebration Pack* (2014), *Grims Goulash Guitar* (2016). Free download for signing up to a Sims newsletter: *Family Portrait* (2018). Free download for signing up for *The Sims Mobile*.

Spin-Off Games: *The Urbz: Sims in the City* (2004), *The Sims Online* (2002), *The Sims Life Stories* (2007), *The Sims Pet Stories* (2007), *The Sims Castaway Stories* (2008), *The Sims Medieval* (2011), *The Sims Medieval: Pirates and Nobles* (2011), *The Sims Social* (2011), *The Sims FreePlay* (2011), *The Sims Mobile* (2018), *MySims* (2007), *MySims Kingdom* (2008), *MySims Agents* (2009), *MySims Camera* (2009), *MySims Racing* (2009), *MySims Party* (2009), *MySims SkyHeroes* (2010).

Simulation Games

Simulation games generally refers to video games that involve the player in controlling several elements of a dynamic system that is modeled by the video game. The distinction being made in this widespread sense of the term would be between games in which the player principally plays through a position situated within the game's world or arena—for instance, through an avatar in a first-person shooting game—and games in which the player spends a significant amount of time operating interface controls that affect the game's world from a position “above” or outside it. In Sid Meier's simulation game classic *Civilization* (1991), for example, the player manipulates a range of variables concerning the ongoing progress of his or her civilization in relation to that of competing ones (run by the game's software or by other players, in later versions offering multiplayer gameplay). These include the direction of scientific research and technological advance, city building and infrastructure choices, diplomatic relations with other civilizations, and military operations and strategy. The player must also respond to environmental variables such as weather, resource availability, and natural catastrophes. A range of interfaces are used in managing all of these tasks, from windows with lists and tables, to dialogue boxes in which either-or choices are made, to a first-person interface with the leaders of foreign

civilizations, to the most characteristic “god game” perspective, looking down on the simulated territory held by your civilization to move units around, develop resources, and conduct military operations.

Although it is always difficult to posit with certainty the first instance of a type of game or indeed any cultural form, *Utopia* (1982) is often taken to be the first video game involving this kind of combination of resource management and strategic turn-based play, although *Stellar Track* (1981), a text-based game published by Sears for the Atari VCS 2600, is another contender for this status of an original strategic simulation, as it was both turn-based and involved limited resource management of weapons, damage, and fuel of the player's Starship avatar. Developed for the Mattel Intellivision, *Utopia* was a two-player turn-based game in which players competed for economic and military supremacy against each other. *The Sims* (2000), designed by Will Wright and part of one of the best-selling video game franchises, is the most well-known simulation game in this sense of the term. Likened by Mary Flanagan to playing with a dollhouse, the game involves the player in managing the everyday activities of a group of simulated human characters, including eating, sleeping, working, and socializing. The player creates the characters' physique and ethnicity, dresses them, manages the household budget, builds and renovates their house, guides them through social and work and study activities in various add-ons, and so on. Will Wright was also the designer of *SimCity* (1989), *SimEarth* (1990), and *SimAnt* (1991). Subsequently, he designed the highly anticipated *Spore* (2008), a

game in which players experiment with a model of genetic evolutionary processes to create their own creatures and compete for galactic supremacy against other species.

Another notable simulation game designer is Peter Molyneux, whose *Black & White* series (beginning in 2001) has the player running a “primitive” civilization both from a God’s-eye view and as a godlike figure whose controlling moves inspire “belief” in the game world’s simulated people. More recently, Johan Andersson and Paradox Development Studio have successfully crafted a reputation for grand strategy titles with fully simulated, procedural narratives with unique characters, families, and politics. Johan Andersson calls this design philosophy one of creating “believable worlds,” and it is exemplified in ongoing series such as *Hearts of Iron*, *Crusader Kings*, and *Europa Universalis*.

Understood in this way, simulation games are a subset of strategy games, another common generic classification of games. Video games studies researchers such as Espen Aarseth have pointed out, however, that, in a way, all video games are simulation games. This is because, first, all games can be approached as simulations that model a system or scenario in an artificially circumscribed zone of playful activity (Johan Huizinga’s idea of the “magic circle” of play is influential here). Second, the digital electronic computer that is the basis of most video games is in essence a simulation machine. The computer simulates other machines along with established techniques and procedures of all kinds. Software configures hardware and interface technology to operate as if it were a typewriter, musical instrument, video editing suite,

digital calculator, telephone, and so on. As a computer game, a video game is always a simulation game of one kind or another.

From this perspective, it is clear that simulation games can also refer to all kinds of other games, such as the sports games that provide the player with a playable model of golf, football, soccer, basketball, tennis, snowboarding, baseball, cricket, and so on. Similarly, flight and vehicle simulation games model the experience of operating a vehicle in its environment, whether that is air, earth, or water. These games usually emphasize audiovisual immersion in the simulated game world, as in aerial combat simulators and racing games. Sophisticated submarine simulations such as *Sub Command: Seawolf-Akula-688(I)* (2001), however, tend more toward a systemic mode of engagement with the environment and its threats through the submarine’s instrumentation, imitating the crew’s tasks and limitations in a real submarine.

In the 1950s and 1960s, cybernetics and systems theory were significant in the development of both the digital computer and the simulations that were designed with it to model and experiment hypothetically with all manner of cultural and natural phenomena. Flight simulation and the strategic-political modeling of thermonuclear conflict were two of the most significant of these simulational developments for the subsequent development of simulation games in both senses of the term described earlier. Researchers such as Ted Friedman, Henry Lowood, and Tim Lenoir have considered how video games reflect the influence of these theories and technical developments, many of which emerged

out of the enormous economic and political investment in military research and development in the anxiety-inducing Cold War climate. Cybernetics conceived of all complex phenomena as a communication system of elements networked together with key points or nodes in which controlling messages could be sent around the network to influence its operation. Systems theory emerged out of statistical methods of analyzing military operations to look for the most successful patterns and the key variables in complex operations such as antisubmarine warfare. It became popular in conjunction with cybernetics as a method of understanding complex phenomena and processes of all kinds, with a view to predicting their outcomes and exploring potential technological and procedural innovations for ensuring control over those outcomes. Simulating the process or phenomena by selectively modeling the salient features of the system with the aid of a computer was a central plank in this method. The computer's calculative power could then be used to run the simulation, modifying the variables and experimenting with different control inputs into the system to gauge their hypothetical effect. As an important element of contemporary computer-based technoculture, video games have profited from these major techno-scientific advances well beyond the confines of the military use of games.

Approaching simulation games in a way that incorporates but also extends beyond the reference to strategic and systemic simulations run from a position of oversight, we could categorize simulation games along two axes. One of these would consider the positioning of the player in relation to the system or

phenomenon being simulated and the other the context or expectation of the users. In regard to the first axis, distinctions could be made, for instance, between games that simulate the dynamics of an environment or sphere of activity, such as a civilization, city, anthill, or a business enterprise in games such as *Theme Park* (1994), and those that situate the player in a scenario with narrative features recognizable from film and literary media. In the former, which is essentially the narrower sense of the term *simulation games*, the simulation models the interaction of diverse elements at the level of the environment or whole system that these interactions influence and constitute. In *Theme Park*, the player manages several variables in attempting to run a successful park: park staff and amenities, types of rides and amusements, pricing, consumer engineering of the space to maximize the flow of the simulated paying customers, weather conditions, and so on. The game is about successfully controlling the development of the amusement park entity at a global level. Success is measured by the sale value of the business, and, having made the sale, the player moves on to a new location to build a better park.

More narrative-based scenario simulations position the player within the game world with an interface that is more about utilizing the world's conditions and reacting to their challenges than managing their overall development. Adventure games, role-playing games (RPGs), many shooting games and tactical team shooters, and vehicle simulations could generally be understood as scenario simulations. From a game design perspective, as Diane Carr pointed out about playing Lara Croft in the game *Tomb*

Raider (1996), a first-person interface is another kind of vehicle the player “pilots.” In these kinds of games, one operates in a simulated space more from an immersed inhabitant perspective. Marie-Laure Ryan’s distinction between objective-and-removed versus immersive-and-engaged kinds of player involvement in virtual worlds is relevant to understanding the difference between scenario and systemic/environmental simulation. In these kinds of games, players have intraworldly abilities and technologies at their disposal, such as movement (walk, crawl, duck, jump, swim, operate a vehicle), techniques, or other actions (open a door, start a fire, administer first aid treatment, radio for an air strike or team extraction, and use weapons and attacks). This list includes virtually embodied or “kinesthetic” interaction as well as other kinds of play “in” a simulated space.

Virtual life simulations, from *The Sims* to massively multiplayer online worlds such as *Second Life* (2003), model a version of everyday living rather than a specific scenario or a discrete environment or system. For some game theorists, these are not really “games” because they do not have goals and rules like a game but rather virtual spaces for imaginative play and for interacting with others socially. The latter can take the form of social networking, virtual communications, and the creation of virtual objects for display, trade, and cultural and political activity. *Second Life*, along with other virtual worlds, has attracted much interest for the way in which these activities in a simulated space have come to resemble and have an impact on real-world society, economics, and politics.

In relation to the second axis along which we could distinguish different

kinds of simulation games according to their context of usage and development, entertainment, education, and training would be the principal categories of use covering most games. We should note that games, like other media forms, can be adopted for purposes their creators did not anticipate. For example, there was considerable controversy when information surfaced that the alleged perpetrators of the 9/11 terrorist attacks had used flight simulation software as part of their preparation for piloting their seized aircraft to their targets in the United States. These “safe” forms of entertainment now seemed sinister and in need of closer scrutiny.

More generally, the popularity of video games as entertainment forms has stimulated widespread research and development in educational games and simulations. So-called serious games, however, should be understood in terms of the longer history of video gaming technology’s expansion from the original military techno-scientific context of simulation development for the serious purposes of training, systems analysis, and strategic simulation. In this regard, 1990s military appropriations of commercial off-the-shelf games, such as the second release in Id Software’s influential *Doom* series, *Doom 2: Hell on Earth* (1995), and Spectrum Holobyte’s fighter jet simulator, *Falcon 3.0* (1991), led the way in showing the potential of commercial video games for serious gaming. However, the *operational games* used widely across social science, urban planning, education, and other disciplines since the 1960s had already established a solid tradition of systems analysis-based gaming in government and other nonentertainment contexts.

Real Lives 2004 (2004) is an interesting educational use of games because of the way it draws on the potential of simulation to project hypothetical events from initial known conditions. It simulates individual existences across the globe in a turn-based game form. Aimed at high school social science students, the game puts the player in the position of having to make important decisions for his or her given life as he or she matures from child to adult. The game is not immersive but informational. It presents the player with challenges based on projected political, socioeconomic, and health factors affecting people in different parts of the world. These are drawn from statistics and databases, such as the World Health Organization, “Human Development” and economic indices, and so on. The player deals with problems facing children growing up in Somalia, Pakistan, or wherever the accident of birth places one at the start of the game.

A less common but nonetheless significant adaptation of video gaming’s simulational potential is its use in critical and artistic registers. Artistic or experimental games is a broad category, but it can include games that use simulation of space, systems, or phenomena in critical and creative ways. In the witty *Kafka-mesto* (2006), the player has to try to exit an urban environment from “1922. Somewhere in Prague. Mid-winter,” by negotiating ominous bureaucratic obstacles derived from Franz Kafka’s novels and stories. More explicitly critical or activist games, such as *September 12th* (2002), use simulation to pose questions about the procedures through which a simulation comes to model a more complex phenomenon. Ian Bogost calls this the “procedural rhetoric” of simulation,

arguing that critical work on and in games as simulational forms must focus on this process of making assumptions about how the simulated world or system works and can be “played.” The risk of the Bush administration’s war on terror strategy—and the way this political logic inhabits the preponderance of military combat video gaming—is the target of *September 12th*’s simple but elegant simulation of a preemptive missile strike against potential terrorist threats that only serves to exacerbate the original problem.

Singapore

Singapore has been the creative hub of Southeast Asia for game development and publishing since 2000. By late 2019, there were around fifty game companies listed in Singapore, the country was ranked the world's second fastest in internet speed, and its game market revenue reached USD 102 million. Among the gaming population of 1.1 million people, most video game users prefer playing mobile games. Singaporeans are the world's most frequent game players,

playing an average of 7.44 game hours per week.

Singapore's development in its game sector benefits from strong government intervention. Since the beginning, the Singaporean government has implemented notable policies, such as *Media 21* (2003), *Intelligent Nation 2015* (2008), and *Infocomm Media 2025* (2015), to grow the industry's ecosystem. The history of the game industry has three stages: the first wave from 1995 to 2000, the second wave in the 2000s, and the third wave in the 2010s (Chung 2015). These three waves mark the country's industrial transition from an emphasis on foreign capital in the early stages to local independent game developers in the most recent stage.

Three offices are in charge of game industry development in Singapore: the Economic Development Board (EDB), the Media Development Authority (MDA), and the Infocomm Development Authority (IDA). These offices worked with other government offices to form multiagency administrative support. On the one hand, the EDB attracted transnational game companies, such as Koei, Lucasfilm, and Ubisoft, to set up Southeast Asian offices in Singapore. On the other hand, the IDA and the MDA facilitated the growth of the local game industry value chain. They also connected locally made games to global and regional distributors in Singapore. While the IDA concentrated on upgrading Singapore's IT infrastructure, the MDA carried out initiatives and grant schemes to cultivate an industry environment for local start-ups. In 2016, the government merged the MDA and the IDA into one office, the Info-Communications Media Development Authority (IMDA). This

merger demonstrates Singapore's decision to position video game policy within the country's wider digitization policy. Game innovation is part of the country's national plan to enhance Singaporean's digital living in the convergence society.

Of the three notable government policies, *Media 21* identified the game industry as one of the country's three focused sectors in Singapore's creative industry development. In this policy, Singapore is envisioned as a global creative-media city. The government planned to create jobs and increase the pay scale for employed workers. Continuous effort was carried on in the *Intelligent Nation 2015* (iN2015) policy, in which the game industry played an increasingly visible role in the country's IT master plan to build a "Smart Nation." This policy adopted smart-city strategies to improve Singapore's influence in the global information/communication sector. The *Info-comm Media 2025* policy required the game industry to carry out further cross-platform innovation. Made-in-Singapore game content started to emerge in the later part of 2000s, when a few government-initiated projects came to fruition.

For instance, the Singapore-MIT Gambit Game Lab implemented a research relationship between Singapore's early developing game industry and prestigious higher education research institutions in both Singapore and the United States. The DigiPen Institute of Technology Singapore introduced a foundation curriculum for game education and began training talented students in game development and design. Many games created through Gambit and DigiPen have won prizes in game competitions. Moreover, Pixel Studio, previously named the Game Solution Center,

serves as a one-stop government resource center that provides incubation support to turn new ideas into prototypes. The studio has a mentor program in which industry leaders share their industry knowledge with local start-ups. The game developers that are supported by the studio are often encouraged to expand their design storytelling to include new platforms of virtual reality (VR) and augmented reality (AR). Pixel Studio lists its services as helping in the areas of design thinking, user experience, digital storytelling, immersive experience, content creation, technological innovation, and game development.

At the industry level, Ubisoft and Koei are two long-lasting global game companies that have been active since their operation. LucasArts' Singapore office had to be closed due to the company's shutdown of its global game unit after Disney's buyout of the company in 2012. However, LucasArts Singapore has thrived in animation production, and the office participated in creating several TV series and movie productions that won Emmy and Oscar awards. Popular films made by these global companies include *Teenage Mutant Ninja Turtles: Turtles in Time Re-Shelled* (2009); *Prince of Persia: The Forgotten Sands* (2010); *Star Wars: The Force Unleashed 2* (2010); *Assassin's Creed: Rogue* (2014); *Assassin's Creed: Unity* (2014); *Nobunaga no Yabou 201X* (2015); *Tom Clancy's The Division* (2016); *Ni Oh* (2017); and *Skull and Bones* (2019).

The growth of local game companies is one significant outcome after more than two decades of industry evolution due to policy intervention. The industry is gradually becoming stable as more start-ups emerge and succeed in becoming notable players in the local game industry.

Industry synergy is transformed by knowledge transfer when local talents leave their previous work at global game companies to set up independent studios in Singapore. While independent game development bears risks to operate in Singapore's industry, active game studios are BattleBrew Productions, Boomzap Entertainment, Daylight Studios, Ratloop Joysteam, Takoway, and Touch Dimensions. Some local companies produce games for distribution through Facebook and Google, which offers an Indie Game Accelerator program. This program provides selected indie game developers from Southeast Asia an opportunity to work in close collaboration with a Google team to access the organization's information for global development for the global market of Google Play.

Singapore's game industry has produced an increasing amount of made-in-Singapore content in the independent game scene. Several local games have won awards in the Independent Games Festival, Xbox Indie Game Festival, Taipei Game Show, and Tokyo Game Show. The list of games receiving awards includes *CarneyVale: ShowTime* (2008), *Armor Valley* (2009), *Rocketbirds: Hard-boiled Chicken* (2011), *Autumn Dynasty* (2012), *Masquerada: Songs and Shadows* (2016), *The Gentlebros* (2017), *Tiltoff* (2017), and *Songbird Symphony* (2019). Some of these are 2-D games that have been recognized for their strong visual presentation of graphic art. Others stand out as rhythmic games known for their soundtracks and musical storytelling. In particular, *Autumn Dynasty* and *Tiltoff* use the concepts of Chinese calligraphy and Tai Chi to enhance player experience. These games altogether present

unique ways to understand Singaporean cultural sensibility, as these games are commercially available and published across multiple platforms, such as Steam, Xbox 360, iOS, Android, Play Station, and Switch.

Lastly, Singapore has emerged as a hub for esports businesses, as esports' popularity is growing rapidly in Southeast Asia. Razor is a global gaming equipment manufacturing company, and Garena is a shopping and gaming platform company. Garena's gaming service, Garena eSports, reaches out to the Southeast Asian market. Both companies are Singapore based and are partially owned by or partnered with China's biggest game company, Tencent.

SNES. See Super Nintendo Entertainment System/Super Famicom

SNK (Shin Nihon Kikaku) Playmore

SNK Playmore is a software (and former hardware) developer from Japan known for its high-quality two-dimensional games, particularly fighting games; numerous arcade games; and the Neo•Geo home console system. The company was founded by Eikichi Kawasaki under the name Shin Nihon Kikaku (Japanese for "New Japan Project") in 1978. Initially begun as a hardware and software

company providing business solutions, SNK soon shifted its focus to producing games for the arcade, starting with *Ozma Wars* (1979). Over the next decade, the company released numerous arcade games, several of which were ported to the Nintendo Entertainment System (NES).

In 1990, SNK introduced the Neo•Geo Multi Video System (MVS), a modular arcade system. The MVS functioned like a home console system in that the games were contained in cartridges that could be easily changed. The cabinets could contain as many as six cartridges at a time, allowing the player to select which game to play. The MVS thus had three major advantages over other contemporary arcade hardware. First, new games could be easily installed. Second, new games were much cheaper than games from other manufacturers because operators only needed to purchase a small plastic cartridge, as opposed to a new stand-alone cabinet. Third, having multiple games in one unit saved valuable floor space. Although other modular arcade systems did exist at the time, notably Data East's DECO cassette system (1980) and Nintendo's PlayChoice-10 (1986), these were aging and lacked the computational power of the MVS. Furthermore, the DECO system's cassettes were famously fragile, and the PlayChoice-10 only offered games already available on the NES. In 1990, one of the major draws of arcade games was their technical superiority to home consoles, and arcade operators relied on a steady influx of new games to bring in customers. Although the MVS was based on old ideas, the advantages it offered over other systems were substantial.

After the success of the MVS, SNK decided that there might be a market for

a high-end home game console powerful enough to compete with arcade games. At the time, home consoles were much less powerful in terms of graphics and sound quality. Porting arcade games to consoles such as the NES and SEGA Genesis meant making significant cuts, leading to noticeably inferior products. As such, SNK decided to release a home version of the MVS, known as the Neo•Geo AES (for "advanced entertainment system").

The AES debuted in the United States in 1990 with a launch price of \$650. This system included two joystick controllers identical to those used on the MVS cabinet. Games were sold for \$200 or more, making the system drastically more expensive than its contemporaries. However, the superior hardware of the AES meant that the games released for it were identical to their arcade counterparts. Despite the system's price tag, SNK continued to manufacture AES units until 1997, and the last official game released for the platform was *Samurai Shodown V Special* (2004), making the AES the longest-running officially supported video game console to date. It should be noted that the AES was designed before games with three-dimensional graphics became mainstream, and its lack of three-dimensional capabilities had a direct impact on the system's gradual decline.

With the arcade market declining and the market for three-dimensional graphics booming, SNK began experiencing financial difficulties in the late 1990s. In 2000, the company was purchased by Japanese pachinko manufacturer Aruze, and it went into bankruptcy in 2001. In the meantime, founder Kawasaki and several executives had left the company to found BrezzaSoft. Kawasaki also

founded another company known as Playmore. After SNK's bankruptcy, the company's intellectual property was sold to a variety of Japanese companies, including BrezzaSoft. Playmore then acquired the former SNK properties and purchased BrezzaSoft outright, reforming as SNK Playmore.

In 2016, SNK Playmore dropped "Playmore," officially changing its corporate name back to SNK.

Social Media

Although *social media*, broadly defined, could include such things as letter writing and the telephone, it usually refers to the phenomenon of networking, interacting, and generating content on the internet on a wide variety of platforms, such as Wikipedia, Twitter, YouTube, and Twitch, among others. These platforms are often described, without distinctions, as Web 2.0, social media, social networking sites, or participatory media. Although similarities exist between these notions, one needs to look at the history of the internet to understand the nuances. The birth and progressive accessibility of the internet during the second half of the twentieth century meant a separation from the top-down, controlled circuit of information associated with traditional media. New media platforms born

during this time enabled different ways of interacting, creating content, and developing social relationships. Usenet was created in 1980 and served as a public discussion media for users around the world. Bulletin board systems (BBSs) were popular until the mid-1990s, helping users exchange messages, files, and news with each other. The end of the 1990s saw a rise in popularity of homepages. Users could personalize their own website and share content with visitors. Then came prominent weblog or "blog" platforms, such as Blogger and LiveJournal. Blogs are used to share personal information with the public. The information is segmented as "entries" ordered by date, with the newest entry being placed at the very top of the blog.

The evolution and popularity of these platforms eventually gave birth to the notion of *Web 2.0*, which predates the term *social media*. As more people gained access to the Internet, Web 2.0 was hailed as a new public sphere where people could debate and exchange ideas without any form of top-down control or mediation. Hence, users could speak out without restrictions, within a space perceived as both neutral and nonregulated. This meant that anyone seeking to share information, tastes, opinions, or content would be given a voice. In other words, Web 2.0 corresponded to the democratization process of creating and spreading information or knowledge. Indeed, the new media of Web 2.0 was designed in a way to encourage user-generated content (UGC) and a do-it-yourself (DIY) ethic, thus giving equal opportunities to everyone. In this sense, users were said to be *empowered*, both on a political and social level (Jarrett 2008). What is more, Web 2.0 commentators raised the fact that

users could now gather in communities as a way to oppose and disrupt prevailing unequal relationships (economic, governmental, etc.).

Additionally, scholars such as Henry Jenkins (2006) and Mark Deuze (2007) have written about the participatory nature and culture of Web 2.0. Users and communities are not only the recipients of extensive and rich information found on the internet but also, and more so, its producers and main contributors. They also share a common objective and passion for the task at hand. Therefore, significant relationships are created between like-minded individuals, and a dynamic of teaching and learning (skills, vocabulary, practices, etc.) has become central to this setting. Furthermore, the efforts made and the nature of the content created is highly valued by the users involved. Web 2.0 fostered the building of networks of people sharing similar interests, creating content, and participating collaboratively for a greater cause. In connection to this phenomenon, new words such as *produser* (producer + user) and *prosumer* (producer + consumer) became popularized, especially by scholars (Bruns 2008; Tapscott and Williams 2008) and different industries. Consumers could now co-create products and services with businesses through Web 2.0.

From then on, this rhetoric of Web 2.0 spread itself and shaped how platforms were being designed and how businesses and users conducted themselves on the internet. Although its precise origins are unclear, the term *social media* became more prominent in the 2000s and built on these promises of Web 2.0. In short, social media exhibit an intensification of the characteristics described above: creating, sharing, and consuming content;

building and expanding communities; and collaborating, networking, and interacting. Various factors can explain this intensification, such as the growing number of people connected to the internet through different devices (mobile phones, computers, video game consoles, etc.) and the intuitive, malleable, and accessible nature of social media. Platforms often designated as social media include Facebook, Twitter, YouTube, Instagram, Reddit, LinkedIn, and many more.

Some social media platforms capitalize on users' involvement, especially social networking sites (SNS), a branch of social media. As the name suggests, these media aim to create and showcase networks between people that know each other (i.e., friends, colleagues, family) or not (e.g., businesses, celebrities, bands). Accordingly, SNSs offer the possibility to connect with an ever-growing number of carefully selected people and to interact with and within multiple networks. Moreover, SNSs centralize many activities in one place: sharing pictures or videos, publishing comments, creating and frequently sustaining a public profile and self-image, reacting to the news or publications from networks in real time, creating closed groups, and so on.

VIDEO GAMES AND SOCIAL MEDIA

The culture of video games has always been closely associated to the birth and evolution of the internet. With the development of online play, communication platforms (BBS, forums, etc.), and modding tools, video games have both influenced and been influenced by the internet and its participatory culture. For example, in multiuser domains (MUDs),

players created and accessed collaborative spaces to play and interact with each other simultaneously. Another illustration would be the community surrounding Id Software's *DOOM* (1993), which used and popularized forums to showcase the game's in-game bugs to Id Software and to share newly created levels and game modifications. As seen in these examples, social media and online video games have, for many years, gone hand in hand; both allow players to meet, interact, and perform diverse actions, and both exemplify the main principles of participatory culture.

Although video games are not considered social media, they nonetheless integrate many communication tools (e.g., text chat) and ways to socialize (e.g., guilds, co-op mode), and the link between social media and video game culture is as strong as ever today. First and foremost, social media allow communities to gather, discuss, and co-create around a particular object of interest: particular video games, game genres, fan practices, and so on; in a sense, social media becomes an extension of these objects. Indeed, communities invest in different social media platforms to collectively reinterpret video game culture, create original content, develop social norms, debate about the "metagame" (the optimal way to play), and so on. Therefore, communities use social media to create their own communal space of discussion and collaboration, which is said to be outside of power relationships.

With this in mind, specific social media platforms are becoming more and more popular for gaming communities. The live video-streaming website Twitch is now one of the central places where people gather to watch players play their

favorite games. Some streamers are now prominent figures and have a large number of fans and, in some cases, even sponsors, and esports competitions are also largely followed there. Twitch is designed so that viewers can participate in many ways and interact with streamers by commenting live, buying "bits" to congratulate the streamer, or subscribing to a channel, among other ways. Following the success of Twitch, YouTube has also launched its own built-in livestreaming platform called YouTube Gaming.

Other than livestreaming, YouTube has been an important platform for gaming culture; many of the most popular videos in YouTube's history are of people playing or creating content with video games. For example, machinima videos have long been published on YouTube and have gained a large following. Let's Play videos (gaming sessions where the performer offers informative, witty, spontaneous, or funny comments) are also one such type of videos popularized through individual personalities or collective channels. Other types of videos that have gained notoriety on YouTube are walkthroughs, step-by-step guides on how to beat a game, and speedruns, where the goal is to beat a game or levels in the shortest time according to community-made rules. In many of these videos, the person playing will include a small window showing his or her facial reactions, and viewers will be able to comment and interact.

As for other types of social media, discussion platforms such as the Steam forums, 4chan, Reddit, and Discord allow players to talk about a variety of subjects surrounding video games. The anonymous, accessible, and participatory nature of these platforms lets users

discuss with ease and often leads to passionate debates. Many communities gather on these platforms to co-create and extend a video game's culture. We can think of memes or fanfic websites where users write about their favorite video game characters and settings. These platforms function through collaborative efforts; feedback and communication are essential aspects. Social media also becomes a space for resistance and protest toward different actors. For example, the "Arab spring," "Occupy Wallstreet," and "Me too" movements gained traction and became "viral"—that is, they spread and reached a wide number of people quickly—in part with social media. The same principle applies to gaming culture; whether it is to criticize a business decision, the use of inappropriate remarks in a livestream, or an illegitimate journalistic practice, communities use social media to raise their concerns. They may also seek to affect in one way or another, for better or worse, the actors involved: calling for a boycott, giving negative reviews on Steam and Metacritic, gaining the attention of traditional media, doxing, or even sending death threats.

Social media are also used to help other players. In this case, more experienced players can teach newcomers how to play and master a game. This is often seen with detailed and extensive wiki sites, FAQs, and walkthroughs. Social media can also prolong gaming experiences, especially with mods; players can either add mods to an existing game or join modding communities to learn how to mod, test mods, give or receive feedback, and share their own creations. Likewise, communities may use social media to assist studios by participating

in early access campaigns, reporting bugs, giving feedback on beta versions, and so on. This is especially the case with small video game studios, which tend to be closer to their communities by interacting frequently with them through social media.

CYBER-UTOPIANISM AND SOCIAL MEDIA

Although social media are celebrated for the opportunities they offer, many problems arise from their usage as well; there is arguably a "cyber-utopianism" (Morozov 2011) regarding social media. Platforms are not neutral, nor do they eliminate power relationships; rather, they are designed according to certain objectives and encourage particular behaviors. This is particularly the case with Facebook, where free social games (e.g., *FarmVille* [2009]) were added to the platform to gain and engage users. Another example would be platforms such as Twitch, where users freely create content and where the proprietary companies can, in many cases, collect, analyze, and sell personal data. Also, user-generated content such as mods can be reappropriated by companies, with or without the creator's consent. This is what Julian Kücklich (2005) calls "playbour": the free, voluntary, amusing, and exploited production of content for a company. Encouraged and facilitated by companies, playbour helps companies reduce costs, prolong a video game's life, gain innovative ideas, and hire creative employees.

Another unattainable ideal is that of equality within communities. Indeed, some users will have a stronger influence and authority within communities. For

example, moderators on forums have the ability to delete posts and orient, consciously or not, the official discourse of their community, and some popular streamers strongly influence the meta aspect of games. The transparent nature of social media can then push players to conform to these discourses and norms, for fear of sanctions, such as exclusion, trolling, intimidation, and the like. What is more, this can lead to echo chambers where communities have specific views about gaming culture, ignoring new or different ideas. Toxicity in social media often operates through this phenomenon. In the end, with its many possibilities and limits, social media acts as an inevitable extension to video games and gaming culture, for better or worse.

Sony Corporation

Sony was founded on May 7, 1946, in Tokyo, Japan, by Akio Morita and Masaru Ibuka and was originally known as Tokyo Tsushin Kogyo Kabushiki Kaisha (Tokyo Telecommunications Engineering Corporation) (Sony Corporation 50th Anniversary Project Team 2002). Sony would go by this name for almost the first ten years of its existence. In 1955, however, the company was about to branch out to the North American market and was concerned that Westerners would have trouble pronouncing the Japanese name. To appeal to the Western market, the company chose the name Sony, not only for its ease of pronunciation and its short length but also because it is similar to the Latin word *sonus*, the root word of *sonic* and *sound*, and is similarity to the word *sonny*, which they hoped would connote a young, energetic, and friendly company (Sony Corporation 50th Anniversary Project Team 2002). The name was so successful that

the company officially changed its name in January 1958.

According to Sony's official history, the company that would become Sony was established in the aftermath of World War II when Ibuka founded a company that repaired radios that had been damaged in the war. Morita was about to accept a job as a lecturer at the Tokyo Institute of Technology when a newspaper published an article featuring his old friend Ibuka's company. Morita wrote Ibuka to congratulate him on his success, and Ibuka wrote back urging Morita to join him. Morita turned down the lecturer job, and a few months later, the new company was formed (Nathan 1999).

Although early Sony products included seat warmers and voltmeters, the products that would be their first success were record player needles manufactured from steel recovered from buildings that had been bombed during the war (Sony Corporation 50th Anniversary Project Team 2002). This product would lead to other products in the field of sound reproduction and recording, including the first tape recorder made in Japan and one of the first transistor radios.

Before the invention of the transistor, radios were made with heavy glass vacuum tubes. Transistors were much smaller and less fragile. Although Sony did not invent the transistor, it was the first Japanese company to make them and the first Japanese company to make transistor radios. Although American company Industrial Development Engineering Associates was the first to release a transistor radio, it bought the transistors from another manufacturer. Sony was the first company in the world to make a transistor radio from the transistors on up (Sony Corporation 50th

Anniversary Project Team 2002). This radio, the TR-55, could fit in a shirt pocket and was at the time the world's smallest radio. Its success meant that radios were suddenly everywhere as well as the Sony name.

The fact that the radios, which were sold not only in Japan but also the United States, had the Sony name is notable because at the time Japanese products were often seen as inferior. Sony had offers from Western companies to sell the radios, but all of them wanted to sell the products under their name rather than the Sony name because it was unknown. Sony refused to take its name off its products, which built the Sony brand and improved the reputation of Japanese-made electronics.

Sony's strong eye for branding and its desire to design and manufacture a product's base components (as in the case of the transistor radio) were both traits that would define Sony for the next several decades. Not content to follow other companies, Sony has a long history of researching and developing its own formats and technologies. Among them are such successful products as the Trinitron television, the Walkman, three-and-a-half-inch floppy diskettes, the compact disc (CD), the DVD, Blu-ray technology, and the PlayStation systems. Of course, this impulse for developing its own technologies has also resulted in some well-known failures, such as Betamax, which was successful within the broadcast industry but lost to the VHS format in the consumer market; the MiniDisc, which was popular among musicians and audio enthusiasts but not among the public (and was made largely obsolete by solid-state and hard drive-based devices such as the iPod); the Memory Stick,

Sony's own solid-state memory, which is rarely used by companies other than Sony; and the UMD, which was used for games and movies in the PlayStation Portable but was phased out by Sony in favor of downloadable content.

Sony is, of course, a major player in the video game industry with its PlayStation line of consoles, handheld gaming devices, and the Sony Online Entertainment division, which has released numerous massively multiplayer online role-playing games (MMORPGs), including *EverQuest* (1999), *Star Wars Galaxies* (2003), *PlanetSide* (2003), and several others.

In addition, Sony is a multinational company worth more than \$172 billion (as of 2018) and is currently involved in practically every aspect of the entertainment industry, from the of televisions, surround-sound home theater equipment, and portable MP3 players to film studios such as Columbia Pictures, television production companies responsible for such shows as *Seinfeld* (1989–98) and *Who Wants to Be a Millionaire* (1999–present), and music studios that release music from a large variety of musicians, including Aerosmith, Will Smith, Santana, and Lady Gaga (Sony 2018). Sony Corporation has a tradition of making innovative and unique products, and there is every indication that tradition will continue through the twenty-first century.

Sony PlayStation

The Sony PlayStation was a CD-ROM-based console that served as Sony's first entry into the home video game market. Although the Sony PlayStation was released in Japan on December 3, 1994, and in North America on September 9, 1995, its history stretches back to 1988, when the system was originally conceived as an add-on device for Nintendo's Super Nintendo Entertainment System (SNES) console. Known as the "Play Station" (two words), the device would allow Nintendo to make CD-ROM-based games (Kent 2001). The PlayStation was only conceived as a stand-alone gaming system in 1991, when, after relations between Sony and Nintendo broke down, Nintendo announced that Philips would be creating the CD-ROM add-on for Nintendo (Kohler 2018).

It was logical for Nintendo to choose to work first with Sony and then Philips because both companies had been influential in the creation of the technologies that would make the PlayStation possible. In October 1982, Sony and Philips released the first compact disc, which

The Sony PlayStation home video game console, with a controller. (Evan-Amos)

not only revolutionized the music industry but also became the storage format for the PlayStation and other disc-based video game systems (Nathan 1999). Although the compact disc was originally released as an audio-only format, Philips and Sony began to extend the format, resulting in the CD-ROM format in 1985, which allowed the disc to contain data, and the CD-i format in 1986, which allowed the discs to contain interactive multimedia content (Desmarais 1992).

Although Sony did release one early CD-i player in 1991, it was around this time that the relationship between Sony and Philips began to sour, and Philips became the main manufacturer of CD-i units (“Philips CD-i” 2007). Although the CD-i format is generally perceived to be a failure, it was one of Sony’s first forays into interactive media, and it was Philips’s role in creating this technology that led Nintendo to partner with Philips when the Sony-Nintendo deal fell apart.

The next stop on the journey to the PlayStation was when Sony executive Ken Kutaragi became interested in working with Nintendo in 1986, after Nintendo had released its Famicom Disk System, a proprietary floppy disk-based

expansion system for the original Nintendo console. At the time, Sony had already released the widely used three-and-a-half-inch floppy disk. Perplexed as to why Nintendo would use an inferior format instead of Sony’s, Kutaragi tried to interest Nintendo in a joint venture with Sony (Asakura 2000). This led to Sony manufacturing the sound chip for Nintendo’s SNES (Valay 2016). All the while, Kutaragi tried to convince Nintendo of the benefits of CD-ROMs over game cartridges, but Nintendo was skeptical because CDs took ten to fifteen seconds to load while cartridges were nearly instantaneous (Valay 2016). According to a former Sony executive, Nintendo did not think the CD-ROM add-on for the SNES would be a success (Valay 2016).

This lack of confidence in the format may be the reason why, in 1988, Nintendo signed an agreement with Sony that allowed Sony to be in charge of the CD-ROM format—including the profits and ability to manufacture its own hardware without any input from Nintendo (IGN Staff 1998; Valay 2016). The name “PlayStation” was picked with the reasoning that if a person worked at a “workstation,” it seemed to make sense that a person would play at a “playstation” (Asakura 2000).

On June 1, 1991, at the Consumer Electronics Show (CES), Sony announced its deal with Nintendo to the world (Shapiro “Nintendo-Philips” 1991). The very next day, Nintendo took the stage and stunned Sony by announcing that it had entered a deal with Philips to create the CD-ROM-based SNES peripheral (Shapiro “Sony” 1991). Although the exact reasons for Nintendo breaking the contract with Sony have never been revealed, many theorize that Nintendo felt that Sony had too much power in the relationship because its deal with Sony allowed Sony to release its own hardware and games (Kohler 2018; Shapiro “Sony” 1991). In the end, Nintendo’s deal with Philips also broke down, and Nintendo would not release a disk-based system until the Nintendo GameCube in 2001. Nintendo’s betrayal also spurred Sony to continue working on the PlayStation on its own (Asakura 2000).

When Sony entered the video game market, it was dominated by Nintendo and SEGA, and its success seemed anything but assured. Even many within Sony were skeptical and thought that Sony should stick to more “serious” products and not enter the video game market (Asakura 2000). The PlayStation’s eventual success in the marketplace was due not only to its technology but also to Sony’s aggressive marketing and licensing deals. The use of compact discs rather than cartridges allowed Sony to utilize the larger 650 MB storage space of the discs and to lower the price it charged other companies to make PlayStation games because compact discs were much cheaper to manufacture than cartridges and had a larger capacity (“How the PlayStation Changed Gaming” 2015; Leone 2018).

What really set the PlayStation apart from the cartridge-based Nintendo 64 and even the disc-based SEGA Saturn was the PlayStation’s emphasis on three-dimensional filled-polygon-based games instead of two-dimensional sprite-based games (Asakura 2000). Other gaming systems used flat two-dimensional game characters and objects known as *sprites*, but the PlayStation was able to use *filled-polygon* graphics to create characters and objects that had depth to them and could be seen from any angle. This made the games seem more lifelike and advanced than the visuals of two-dimensional games. Although both SEGA’s and Nintendo’s consoles could do this as well, they were seen as less powerful and in some ways harder to program for, and did not emphasize polygonal graphics from the start (“How the PlayStation Changed Gaming” 2015; Thorpe 2018).

The PlayStation firmly established Sony’s place in the gaming world, leading to the PlayStation 2 (PS2), PlayStation 3 (PS3), and PlayStation 4 (PS4) as well as the PlayStation Portable (PSP) and PlayStation Vita (PS Vita or Vita). By the time the PlayStation was discontinued in November 2006, Sony had sold more than 102 million consoles, nearly eight thousand games had been released for it, and consumers had purchased nearly one billion discs (Sony Computer Entertainment 2011; Sony Computer Entertainment “Cumulative Production” 2008; Sony Computer Entertainment “Cumulative Software” 2008). Its success led to the death of cartridge-based home video game consoles, eventually forced SEGA to stop manufacturing hardware, and popularized home gaming with three-dimensional graphics.

Sony PlayStation 2

More than simply a newer version of the original Sony PlayStation, the PlayStation 2 (PS2) has sold almost 158 units as of September 2020, making it the most

successful video game console ever made (“Global Unit Sales of PlayStation 2 as of September 2020, by Region” 2020). First released in Japan on March 4, 2000, and in North America on October 26, 2000, the PS2 was the original platform for such landmark games as *Grand Theft Auto III* (2001), *Katamari Damacy* (2004), *Guitar Hero* (2005), and *God of War* (2005) (McCarthy 2006). Remarkably, the PS2 continued to be manufactured until January 4, 2013, well after other systems of its generation had ceased being sold. It is a testament to the staying power of the PS2 that the last game officially released for the system, *Pro Evolution Soccer 2014*, was released in November 2013, the same month as the PlayStation 4 (Crawley 2014).

Although the first PlayStation used CD-ROMs as the storage medium for its video games, the PS2 used DVDs, which not only allowed for much more information to be stored on a single disc but also meant the system could play DVD movies. When the PS2 was first released, DVD players were still fairly expensive and were not as ubiquitous as they are now, so the PS2’s ability to play DVDs was a strong selling point (Kent 2004; McCarthy 2006; Stuart 2013). The PS2’s processor was a custom one codeveloped by Sony and Toshiba that they dubbed the “Emotion Engine.” Containing 10.5 million transistors and eight separate processing units, this processor is capable of 6.2 billion floating point operations per second (Diefendorff 1999). This made the PS2 so powerful that scientists at the National Center for Supercomputing Applications (NCSA) combined seventy of them to create a supercomputer, and Iraq was rumored to have imported thousands of PS2s to use them in guided

missiles (Farah 2000; Markoff 2003). However, the Emotion Engine was also very complex. Some said that the PS2 was so complex and unlike traditional computers that programming it was very difficult; many game delays were blamed on the complexity of the Emotion Engine (Kent 2004).

This complexity may have hurt development, but it did not hurt its sales. With such high sales, it was inevitable that a number of add-ons and peripherals would be released for the system. One of the most popular add-ons for the PS2 was the PlayStation Network Adapter. When the PS2 was released in 2000, it did not come with internet connectivity. The network adapter was released in 2001, and it allowed players to play online with and against other players. Perhaps more importantly, the network adapter also allowed players to install a hard drive into the PS2. Although few games used the hard drive, it was an ability that brought the PS2 into parity with the Microsoft Xbox, which had internet connectivity and a hard drive as standard features. When Sony released the “slim” version of the PS2 in 2004, it integrated the Ethernet port, making the add-on unnecessary, and eliminated the expansion port that allowed a hard drive to be installed (PlayStation 2002).

One of the most groundbreaking peripherals for the PS2 was the EyeToy. Released in 2003, the EyeToy was a camera that allowed the PS2 to “see” the player and allowed the player to interact with on-screen game elements by moving his or her body in a manner similar to what would later appear in the Xbox Kinect (PlayStation Underground 2003). This technology would continue to be used on the PlayStation 3 (PS3) under the

name PlayStation Eye. The PlayStation Eye and the PlayStation Motion Controller are the basis of the PlayStation Move technology, which is a motion controller technology similar to that used by the Nintendo Wii (Kent 2004; Marks 2010).

Another highly successful peripheral that was first released for the PS2 but would later be released for practically all video game systems is the guitar-shaped controller used by the *Guitar Hero* series of games. Released in November 2005 in North America, the original *Guitar Hero* game came with a controller roughly three-quarters the size of a real electric guitar. Although there were earlier guitar-inspired arcade games, it was the PS2 that first brought the instrument-based rhythm games to popularity in North America, and *Guitar Hero* sequels and spin-off games would be released for other systems.

When the PS2 was released in Japan and then in North America, the demand far exceeded the supply (McCarthy 2006). With stores quickly selling out, units could be found for sale at online sites such as eBay for as much as \$1,000. There was even a report that one boy in Japan was so disappointed he could not get a PS2 that he committed suicide (Kent 2004). Although SEGA hoped that it could capitalize on the PS2 shortage by selling more of the Dreamcast consoles, it was unable to do so, and on January 31, 2001, SEGA announced that it would stop making gaming hardware (Kent 2001).

Although Sony has stopped selling the PS2, the number of consoles sold and the number of games made for the system ensure that it will be remembered as a high-water mark for home video game consoles.

Sony PlayStation 3

Sony Computer Entertainment's (SCE) PlayStation 3 (PS3) is part of the seventh generation of video game consoles, alongside the Nintendo Wii and the Microsoft Xbox 360. SCE released the PS3 in 2006, on November 11 in Japan and November 17 in North America. Because of a shortage in the materials required to produce the newly developed Blu-ray optical drive, these release dates were not only much later than originally anticipated, but the number of units produced fell short of SCE's target by 50

percent (lup.com 2006). Consequently, the releases for Europe and Oceania would only begin in March of the next year. Although shortages are common among hardware releases, the Xbox 360 sold 75 percent more consoles during its initial launch than SCE did with the PS3. Worldwide, the PS3 has sold more than thirty-five million consoles, roughly five million less than the Xbox 360, although this margin has been narrowing.

Sony Corporation (SCE's parent company) promoted the optical drive as part of its professed strategy to promote high-resolution film and gameplay, eventually leading to the development of its 3-D hardware equivalents. Sony, meanwhile, would capitalize by synergistically selling high-definition televisions and eventually 3-D TVs (Greenfeld 2010). Without the drive, the data transfer from disc to screen would be too slow and require too many discs. However, given the relative cost to produce the drives—in materials, delays, and sales—a heavy burden was placed on Sony, which priced the PS3 at \$399 and \$499 (the latter sold at more than \$300 below cost), \$100 more than the Xbox 360 (Quilty-Harper 2006). To compare, Blu-ray players without the hard drive, graphics processor unit (GPU), and central processing unit (CPU) were sold for the same price.

The reason for this discrepancy, beyond the Blu-ray drive, is the CPU. Developed by Sony, Toshiba, and IBM, the PS3's Cell processor boasts a unique and costly architecture. Both the PS3 and Xbox 360 have a core processor based on IBM's 970 PowerPC, but the PS3's is purposed to delegate tasks to eight other processors, the Synergistic Processing Elements (SPEs). Although the GPU, the RSX: Reality Synthesizer,

is somewhat inferior to the Xbox 360's GPU, it can still render HD images and outperform the Xbox 360 by unloading its processing burdens to the Cell processor. This new architecture was projected to be useful in the future of programming, allowing for a comparatively high number of calculations per second, but it consequently stunted the early development of games because of the increased difficulty to optimally program it, a problem furthered by Sony's later admitted lack of available programming libraries ("Q&A" 2010). In addition to forcing an advancement in software design, the processor has been used to exemplify "the boundaries in computer technology that are being pushed by the demand for video games" (Crandall and Sidak 2006).

To mitigate the perceived cost, SCE designed the PS3 to act as a multimedia computer, enabling Blu-ray and DVD film viewing, web browsing, music and photograph display and storage, and online video chat. What is more, it enabled the PS3 to be backward compatible, able to play games from the PlayStation and the PlayStation 2 (PS2), and work as a Linux machine. With Linux installed, the PS3 could additionally work with scientific research by contributing remote processing power. With time, however, SCE removed the backward compatibility for PS2 games and other operating systems and went so far as to release a firmware update stopping any Linux-installed machine from working. Although its hardware changed during its operational lifetime, varying its size and hard drive space, its processing power remained stable, ensuring that all versions of the PS3 could play the same PS3 games.

The PS3's game controller, dubbed the DualShock 3, looked nearly identical to its

predecessor, the DualShock 2, but it featured accelerometers capable of detecting movement on six axes, providing opportunities for game developers to have players produce different trackable gestures. In addition, the PS3 was able to handle seven operational controllers at once; however, there were fewer than a dozen games that allowed for more than four local players. With the release of the PS3, Sony launched the PlayStation Network, from which players could download games, updates, extra content, and play with others online. Unlike the Xbox 360's network, there was no monthly fee, ultimately resulting in less functionality and fewer services.

The initial set of games released alongside the PS3 totaled a dozen because many were delayed, and one, *NBA Live 07* (EA Sports, 2006), was canceled. Of these releases, only four were PS3 exclusive: *Genji: Days of the Blade* (SCEI, 2006), *Untold Legends: Dark Kingdom* (Sony Online Entertainment, 2006), *Mobile Suit Gundam: Crossfire* (Namco Bandai Games, 2006), and *Ridge Racer 7* (Namco Bandai Games, 2006). These fared somewhat poorly, and because of the delay in the PS3's release, the cost of its hardware, and competition from the Xbox 360, SCE lost a large portion of the market share it had previously taken from Nintendo and SEGA in 1994 with the PSX and again in 2001 with the PS2. Its sales would recover in 2009 with its redesigned hardware, nicknamed the PS3 "Slim"; its \$200 price reduction; and the critical mass of high-budget proprietary releases such as *Little Big Planet* (Media Molecule, 2008), *Metal Gear Solid 4* (Kojima Productions, 2008), *Demons' Souls* (From Software, 2009), *Uncharted 2* (Naughty Dog, 2009), *Final Fantasy XIII* (Square Enix, 2010), and *God of War*

III (Santa Monica Studio, 2010). Critically, these games placed the PS3 as the console with the most exclusive titles having won Game of the Year from nearly all video game reviewing websites and magazines. With this shift toward profitability came a new logo and the slogan “It Only Does Everything.” From this campaign, a second slogan emerged with the announcement of the PlayStation Move at the 2010 Entertainment Electronics Exposition: “This Changes Everything.”

The PlayStation Move was a new controller meant to provide physical affordances otherwise untracked by the DualShock 3. The Move most closely resembled Nintendo’s Wiimote—but with fewer buttons—with an analog trigger and a glowing LED orb capable of being tracked by the PlayStation Eye (SCE’s previously released webcam). Because of its distinct spherical shape, the PS Eye could track the Move in three dimensions, correlating the captured size with a distance from the camera. This tracking was doubled by an internal gyroscope and embedded accelerometers, enabling new forms of precision of which the Wii was incapable. In addition, SCE announced the addition of a “sub-controller” to supplement the PS Move, much like Nintendo’s Nunchuk for the Wiimote. Although the PS Eye had been used for gestural interfaces, it saw limited success, although with the release of the Xbox 360’s Kinect, a motion-sensing set of cameras used for gestural interfaces, it found a small resurgence with full-body tracking for *Kung-Fu Live* (2010) and head tracking for *Gran Turismo 5* (2010).

The addition of motion control in console gaming was been touted as a means to further extend the life cycles of the PS3 and Xbox 360. Although console

generations have historically lasted only five years before being replaced by newer models, the PS3’s generation was thought to break that pattern and continue past a seven-year mark (Ivan 2009).

Sony PlayStation 4

The Sony PlayStation 4 (PS4) is part of the eighth generation of video game consoles, alongside the Nintendo Wii U and the

Microsoft Xbox One. The PS4 was developed and released by Sony Interactive Entertainment (SIE), which represents the entire PlayStation brand, including hardware, software, content, and network operations. In 2016, Sony merged two of its entertainment businesses, Sony Computer Entertainment and Sony Network Entertainment, to form Sony Interactive Entertainment. Furthermore, the headquarters for SIE was moved to San Mateo, California. Sony Computer Entertainment was founded in 1993 to launch the original PlayStation, and since then, it had been headquartered in Tokyo. According to Kohler (2016), this change in headquarters signals a shift in priorities and business of the PlayStation system, including not only the console but also the services it provides, such as online gaming and streaming services.

The PS4 was launched on November 15, 2013, in North America; November 29 in Europe, Latin America, and Australia; December 2013 in other Asian regions; and February 22, 2014, in Japan. Physical editions of PS4 games come on Blu-ray discs, and the console can read movies on Blu-ray discs and also supports DVD playback. Eric Lempel (2018), the senior vice president of PlayStation Worldwide Marketing, states that more than 86.1 million hardware units and over 777.9 million software units have been sold worldwide. The PS4 had several new features that enhanced the gaming experience; it emphasized the social aspects of gaming by allowing players to stream gameplay sessions online, and it also introduced a redesigned and improved controller.

The PS4's DualShock 4 wireless controller had several new features that distinguished this controller from its

predecessors. The analog sticks and triggers had been refined, and their surface was concave, similar to the ones found in an Xbox 360 controller. The traditional "Start" and "Select" buttons were merged into a single "Options" button, which allowed players to pause games and access the game menu. The "Share" button allowed players to upload gameplay videos and screenshots directly from the PS4 system. Moreover, players could livestream their gameplay without interrupting the game itself, and they could use "Share Play" to share game screens with other players in a party while playing. Other new features included the touchpad, a capacitive panel meant to add supplementary interactions within games. In *Killzone: Shadow Fall* (2013), the personal attack drone OWL can be controlled using the touchpad, which also provides access to the drone's several modes. However, very few games have used the touchpad since the launch of the PS4, and it is mostly used to access in-game menus.

The DualShock 4 has a light bar that changes color depending on the different situations players encounter during gameplay. For example, while playing the remastered version of *Spyro the Dragon* that is part of the *Spyro Reignited Trilogy* (2018), the light bar changes color according to the health of Sparx, Spyro's companion. The controller also has a built-in speaker that allows sound effects to come directly from the controller. The feature is used, for example, in *Spelunky* (2014), where the location of the damsels in distress is signaled by the sounds they make, and they are heard through the speaker in the controller. The controller also has a stereo headset jack that allows players to connect their headphones directly to

the controller. The DualShock 4 has motion sensors already installed, without the need of an additional controller, such as the PlayStation Move controller. The physical affordances can be seen in games such as *The Walking Dead: The Final Season* (2018), where players have to tilt and rotate the controller during certain points of the game, mostly in sequences that involve fighting zombies.

When it was first launched, the PS4 was available with a 500 GB hard disk drive. Since then, two redesigned models have been released, including the PS4 Slim and the PS4 Pro. The PS4 Slim was released on September 15, 2016, and is 40 percent smaller in size than the original PS4 model. It was sold at the same price as the original version of the PS4, also with 500 GB of memory. A model with 1 TB was later released, with no change in price. In general terms, there are very few changes between the original PS4 and the PS4 Slim. According to Walton (2016), this version is mostly a less expensive, better-looking PS4, and the console to buy for users new to the system. A few months later, on November 10, 2016, the PS4 Pro was launched worldwide. It is an upgraded version of the PS4, with improved hardware to render 4K, which is high-definition (HD) video that has four times the resolution of 1080p HD video. It is also compatible with HDR television sets and offers impressive graphical details in the latest games developed for the PS4.

The PS4 stands out from other eighth-generation consoles because of its price, its virtual reality (VR) compatibility and library, and its exclusive games. Even seven years after launch, PS4 Slim and PS4 Pro are less expensive than their Microsoft counterparts, Xbox One S and

Xbox One X. The PlayStation VR is a VR headset that offers 360-degree vision, 120 frames per second, 3-D audio, and a built-in microphone. It also includes the PlayStation camera, which tracks the position of the headset, and *PlayStation VR Worlds* (2016), a collection of five different VR experiences. Moreover, some of the most well-known and well-received titles for the PS4 have found their way into the PlayStation VR library, such as *Resident Evil 7: Biohazard* (2017), *DOOM VFR* (2017), *The Elder Scrolls V: Skyrim* (2017), and *Borderlands 2 VR* (2018). Finally, another considerable advantage of this console is its vast library of exclusive games. Among the exclusive titles for the PS4 are *God of War* (2018), *Marvel's Spider-Man* (2018), *Bloodborne* (2015), and *Horizon Zero Dawn* (2017), to mention just a few. These games have been critically acclaimed, and most of them have won several game awards. Other exclusive releases include *The Last of Us: Part II* (2019), an action-adventure game and the sequel to the equally acclaimed *The Last of Us* (2014), and *Death Stranding*, an action game developed by Kojima productions. The PS4 far exceeded the expectations it created at launch, and it was succeeded by the PlayStation 5 in November of 2020.

Sony v. Bleem

The outcome of the 2000 court case *Sony v. Bleem* is useful for the video game industry as well as scholars and publishers who publish work about video games. The case established that the use of screenshots from video games falls within the boundaries of fair use even when that use is *commercial* and even when that use is *hostile*. Thus, scholars and publishers need not ask for permission to use screenshots in their work.

The case arose when Bleem, a company that produced emulation software for playing games for the Sony PlayStation on personal computers, released advertising in which it compared screenshots from the PlayStation with imagery of the same games from its emulator, hoping to demonstrate that the increased resolution available on a computer produced a game image better than the PlayStation itself did. Sony sued Bleem for

intellectual property violations, one of which was the claim that using Sony’s imagery in its advertising violated the copyright on those images. Bleem maintained that comparative advertising fell within fair use.

The court looked at the four factors established in the 1976 Copyright Act:

(a) the purpose and character of the use, including whether such use is of a commercial nature or is for nonprofit educational purposes; (b) the nature of the copyrighted work; (c) the amount and substantiality of the portion used in relation to the copyrighted work as a whole; and (d) the effect of the use upon the potential market for or value of the copyrighted work.

In the end, the court found in Bleem’s favor, ruling that the use of a screenshot (which it refers to at one point as “an inanimate sliver of a game”) does not require permission.

The case ended with the court concluding the following:

It is a fair use for Bleem to advertise comparatively only between what PlayStation games actually look like on a television and what they actually look like on a computer when played with the emulator. It is in this context alone that the comparison is necessarily Sony specific. Otherwise, Bleem must be content to make its comparison without using another’s copyrighted material. We are persuaded by the need for Bleem to impose minimally upon Sony’s copyright with respect to these screen shots because there is no other way to create a truly accurate comparison for the user. The way of simulations is a slippery one for Bleem and if it chooses to embark upon it, it must do so without the support of Sony’s copyright. With that

limitation in mind, we conclude that Bleem's use of Sony's copyrighted material was fair. (*Sony Computer Entertainment America Inc v. Bleem LLC* May 4, 2000)

Although Sony lost on all counts to Bleem about the use of Sony screenshots on its packaging, the legal fees involved in the litigation were too much for the small company to bear and apparently the cause of Bleem's filing for bankruptcy and going out of business.

Sound

Along with graphics, sound provides information needed for gameplay, reinforces agency, and aids the induction of a vast spectrum of emotions, which, in turn, impact the gamers' decision-making processes and sense of involvement or immersion. Therefore, a game's sonic aesthetic results from the need to support gameplay (both from cognitive and affective standpoints) and often to elicit a strong feeling of presence or sense of place within a game world (Jørgensen 2008). That said, many other internal and external factors intervene in the creation of a sonic aesthetic.

From the simple sounds of early arcade games (which often used sound to attract players) to the most sophisticated digital signal processing (DSP), sound has always been constrained by technology.

Yet, according to Karen Collins, the sonic aesthetic of video games is not purely a product of hard technological determinism; the relationship between technology and games should be envisioned as an ongoing mutual influence (Collins 2008, 5). Designers work around technological constraints as technology continues to develop. For instance, in the 8-bit era, music looping was one method used by designers to circumvent memory limitations, but today it is often considered an outdated way to score a video game. Other techniques in interactive and adaptive music have thus been developed to address the growing expectations of designers and the gaming community (see Audio [Dynamic, Interactive, and Adaptive]). In 1991, for example, LucasArts' Michael Land (collaborating with Peter McConnell) developed iMUSE, an interactive music system that allowed closer synchronization between musical cues and in-game events. Land wanted music to respond to unpredictable interactive events and transition more subtly between themes. The desire for better game audio has motivated technological development, which has, in turn, helped sound evolve; at the same time, technological constraints have often given games a unique sound aesthetic.

Economic and ideological factors have also come into play, as games' budgets, development time, and the creativity of designers vary. The sound of a low-budget game might be done by a single person (in the early days of video game history, all sound was done by the game programmer), whereas the sound department of a big-budget game may include a sound director, sound designers, composers, and audio programmers as well as dialogue and voice-over artists.

Market demands and demographics also factor in: differing age groups, casual versus hardcore gamers, and so on. The cultural context in which a game is designed and the impact of international distribution cannot be overlooked. Eastern and Western games tend to differ on many points, starting with the type of gameplay and fictions they propose. Accordingly, sound has to fulfill different tasks.

For a meaningful experience, audio must supply feedback on the game state and stimulate the gamer's listening strategies. In *PONG* (1972), the characteristic "ping" was used to indicate that the ball had rebounded off either the gamer's paddle or one of the horizontal walls delimiting the game's boundaries. While helping the gamer to better evaluate how to react in a given situation, it also provided a sense of rhythm to the game, making it more enjoyable. Most games require sound to fill similar functions, and in the extreme case of audio games, sound structures the whole gameplay experience.

Of course, not all video games are as abstract as *PONG*, *Tetris* (1985), or *Lumines* (2005); many take place in rich, vast, and complex virtual worlds. Consequently, researchers developed concepts and tools to analyze sound according to the specificities of the worlds found in video games. For her part, Kristine Jørgensen, following the ecological approach valued by Mark Grimshaw (2008), proposes the expression "game-worlds"; that is, "environments for play built around the logic of games" (Jørgensen 2017, 75). In such (acoustic) ecologies, sound becomes "an index of the interactions that happen in the environment" (75). In that respect, it must, on

the one hand, render the acoustic traits of said gameworld, often making use of sonic effects simulating the properties of our physical reality—or those that gamers might expect from other types of representational mimetic spaces (i.e., the cine-real [see Collins 2008, 147] effects of a film diegesis). On the other hand, sound must perpetually communicate all the necessary information needed for the gamer's understanding and participation within the ecology, sometimes straying away from a more realistic depiction of the gameworld. This dual identity of gameworlds (ludic and fictional) lead Jørgensen to distinguish *ecological* sounds (that "are directly associated with the gameworld's ecology, and have a close verisimilitude to sounds in the physical world) from *emphatic* ones (which correspond to sound that "augment an event in the gameworld, and provide additional information compared to an ecological sound" [Jørgensen 2017, 79]). To be even more specific, sounds from both categories are dubbed as "fictionally motivated" if they tend to favor fictional coherence, while sounds that do not, often because they need to "clearly communicate gameplay mechanics or achieved goals" (80), are considered "ludically motivated."

Jørgensen's terminology, developed from an obvious and disclosed ecology-centric approach, underlines the fact that, while many video games present gameworlds, they all remain systemic and logical ludic spaces. However, this worldly bias fails to encompass (or at least forefront) games that mostly depict this latter type of space. This, of course, holds true for the abstract and purely systemic games previously mentioned and also for games that present a

gameworld but in which said gameworld does not represent the foregrounded experience. In that respect, it should be acknowledged that the nature and composition of videoludic sound depend on the configurations by which these concurring spatial paradigms (ecological and logical) are layered and experienced and by the way in which they help structure listening.

Genre, understood here as a regulator of formal expression and expectations, then considerably influences a game's sonic aesthetic, particularly according to the conventions associated with the type of phenomenological space—whether logical or ecological—they traditionally aim to present. For example, in the fast-paced action sequences of first-person shooting games, sound must quickly provide information about the player character's surroundings, locating enemies and environmental hazards. Sound must therefore be designed to fulfill forewarning as well as spatial and localization functions (Grimshaw 2008). In survival horror games, sound is used to elicit fear and feelings of dread and uneasiness, and because fear is often induced through the unknown and the uncertain, sound design is conceived so the forewarning and localization functions of sound seem unreliable (Roux-Girard 2010).

Role-playing games (RPGs) do not rely as much on forewarning; for example, in games of the *Final Fantasy* and *Dragon Quest* series, combat is often kept separate from the exploratory sequences of gameplay and is triggered randomly. In turn-based games, gamers have more time to evaluate moves and plan attacks, and with the extended time frame, there is often a richer and more varied score; avoiding repetition is very important to

maintain gamers' interest in the gameworld they explore. So, despite these discrepancies, first-person shooter (FPS), survival horror, and modern RPG games are nevertheless designed in a way that allows for the gamers to experience a sense of place, as if they were directly present or active within the gameworld. And it is according to those experiential ecological parameters that sound should be analyzed.

On the other hand, strategy games, such as those of the *Civilization* series, while still presenting some kind of gameworld, tend to stimulate listening strategies closer to the representation of a systemic, logical space—managed, rather than lived. In this sense, in such games, sounds should not be considered *ludically motivated* or *emphatic* as they simply aim, through the design of their effects, to stimulate a more semantic type of listening in the gamer. Sound is tailored to represent the relationships between the elements of the semantically coded space of the game first and the properties associated with the gameworld (as a place) second. In these circumstances, sound design depends less on how the world is architecturally structured and feels, but rather on what the sounds imply from a strategic standpoint. In other words, these games simply appeal to a more semantic—and less indexical—phenomenological listening paradigm than gameworld-oriented games.

Nevertheless—both in systemic and gameworld-oriented games—the sound aesthetic of video games is quite specific to the properties of the medium. Interactivity achieved through play is the distinctive feature that separates video games from other media. Consequently,

the dynamic nature of video games considerably modifies the relationship gamers maintain with sound. As Karen Collins explains,

Unlike the consumption of many other forms of media in which the audience is a more passive “receiver” of a sound signal, game players play an active role in the triggering of the sound events in the game. While they are still, in a sense, the receiver of the end sound signal, they are also partly the transmitter of that signal, playing an active role in the triggering and timing of these audio events. (Collins 2008, 3)

Indeed, listening to a video game is in many respects different from listening to a movie. For example, a game’s listening point is almost always fixed within the perception of the player character or based on the distance between the player character and the virtual camera. Indeed, a listening point anchored within the subjectivity of a player character is essential to the interaction and identification between the player character and the gamers, facilitating the transmission of affects and emotions.

Interactivity also has a considerable impact on the construction of the on-screen and the acousmatic zones (off-screen and off), as defined by Michel Chion (1990). Whereas the location of sounds in film are determined and fixed by the director, in games, the circuit between on-screen and off-screen is significantly altered by the gamer’s control of his or her player character and, consequently, of the game’s virtual camera. Depending on the sound and context, the gamer may decide to go find the sound’s source or avoid it. Sound designers must therefore strategically use sounds to

properly stimulate gamers’ listening strategies so as to simplify or complicate their decisions.

Of course, this does not imply that the sonic theory developed in music or film studies (or any other field) is irrelevant, but, rather, that it should be used with caution when it comes to games and only be used when applicable (i.e., in the case of gameworld-oriented games). Cinematic sequences in games, for instance, still make use of cinematic conventions. Also, although the relationship between the medium and the audience is considerably modified by interactivity, some of the connections between the images and sounds remain like that of film; they are tightly linked, producing an effect of *added value*. This is described by Michel Chion as a “sensory, informative, semantic, narrative, structural, or expressive value that a sound heard during a scene leads us to project on the image, creating the impression that we see in this image what in reality we ‘audio-see’” (Chion 2003, 436, freely translated). However, the synchronization points responsible for this effect must establish a feeling of causality not only among the image, sounds, and game events but also between the actions performed by the gamer and those performed by the player character within the game’s world. In video games, synchronization points are not only aesthetic but also pragmatic.

Also, in gameworld-oriented games, as in film, the rendering of the sounds must create the necessary degree of plausibility for the sound to seem “real, efficient, and adapted” to “recreate the sensation . . . associated to the cause or to the circumstance evoked in the [game]” (Chion 1990, 94, freely translated).

Overall, the many factors that influence a game’s sonic aesthetic are not

independent but must be understood as an interdependent whole. The sonic aesthetic of video games is ultimately tied to the properties of the medium and is the direct consequence of the different choices made in regard to the context in which a game is designed, toward creating the best possible video game experience.

Sound Technology

Sound technology in video games consists of both hardware and software. The sound hardware sets the limitations in terms of sound synthesis types, stereo and digital signal processing effects, and simultaneous channels, and the associated computer hardware (such as RAM) sets the limitations in terms of how this sound will function in real time in the context of the game and its associated requirements for memory. The software receives information from the game or its interface controls and sends calls to the hardware to activate the sound.

In the very early days of arcade sound technology, the hardware was analog, although this sound was typically controlled and manipulated digitally. Analog sound technology records and produces the electrical output of sound waves as they occur, whereas digital sound technology breaks the information down into binary digits and stores that numerical information so that it can later reproduce the sound.

Analog sound was generated using the speakers, which were "on-board," meaning they were attached directly to the motherboard. These would usually be piezoelectric or electromechanical speakers, colloquially referred to as "beepers," because a "beep" was about all they could handle. Piezoelectric speakers generated sound using a small diaphragm, which consisted of a small ceramic plate with electrodes on both sides attached to a metal plate. A DC voltage was applied between the electrodes on the diaphragm,

causing a mechanical distortion and bending the diaphragm back and forth, creating a sound wave. Sound can therefore be generated by turning the piezoelectric speaker on and off in rapid succession, bending the diaphragm many times a second. An 11 kHz tone, for example, requires the speaker to be turned on and off eleven thousand times per second. Electromagnetic speakers worked in a similar way, using two magnets to create a repulsion and attraction, pushing and pulling the speaker cone, with the frequency and amplitude of the input wave dictating the rate and distance that the speaker voice coil moves and therefore the frequency of sound.

This sound-producing capability could be improved slightly by using what is known as *pulse width modulation*, which controlled the analog circuit with the digital computer timer. In other words, it was possible to digitally encode the analog sound through the use of high-resolution counters. Because the speaker could produce two sound levels (on and off), it was possible to carefully time the pulses of sound waves so that the speaker was left in the “off” position for a fraction of a millisecond, making it possible to emit sounds in between those two on/off levels and thereby increase the possible frequencies.

By the late 1970s, however, dedicated sound chips became incorporated into the hardware of video games. These sound chips have developed over time, incorporating a variety of synthesis technologies. The earliest dedicated sound chips were known as programmable sound generators (PSGs) and used subtractive synthesis, in which an oscillator creates a waveform and then uses a filter to subtract frequencies from that

waveform until the desired frequencies remain. These waveforms were then passed through an envelope generator that would dictate the amplitude shape of the waveform. Many video game PSGs were created by Texas Instruments or General Instruments and contained three-tone generators and one noise generator. Some companies, such as Atari and Commodore, designed their own sound chips. The most popular was the AY-8910 series of General Instruments chips that found its way into a variety of home computers and game consoles, including the Sinclair ZX Spectrum, Amstrad CPC, Mattel Intellivision, Atari ST, and SEGA Master System.

By the arrival of 16-bit technology in the late 1980s, many companies were licensing Yamaha’s Frequency Modulation (FM) synthesis chips, although many continued to also use PSG chips for sound effects, as with the SEGA Genesis, which used both an FM (the YM2612) and a PSG (Texas Instruments SN76489) sound chip. FM combined sound waves, using a modulating wave signal to change the pitch of a second sound wave. Many FM chips used four or six different oscillators for each sound to generate more complex sounds and realistic-sounding instruments. These chips found their way into many of the arcade games of the mid to late 1980s and most computer sound cards of the era.

Add-on third-party FM sound cards were developed in the mid-1980s, notably the AdLib Multimedia card in 1986. AdLib based its card on the nine-channel Yamaha FM chip, YM3812, which was a later version of the popular YM3526 used in many arcade games. Soon after the development of AdLib sound cards,

Creative Technology (now Creative Labs) entered the market with its own sound cards, including Sound Blaster, essentially a copy of the AdLib card, using the same FM chip but with added digital audio capabilities for sampling and, most importantly, a game port. Sound Blaster quickly became the standard for game sound after a drop in price but was soon followed by a flood of sound cards entering the market. With such a variety, programming music for games became more problematic. By 1989, at the behest of Microsoft, Yamaha made its FM chips available on the open market so that a standard sound format for PCs could be created.

Also introduced in the 16-bit era, *wavetable synthesis* used preset digital samples of instruments (usually combined with basic waveforms of subtractive synthesis) and was therefore closer in sound to real instruments than FM synthesis. Wavetable synthesis formed the basis of the Sony SPC-700 sound chip in the Super Nintendo Entertainment System (SNES) and also found its way into Roland's popular MT-32 gaming and music sound card that was released in 1987.

By the early 1990s, most home computers had FM or wavetable sound cards supporting the Musical Instrument Digital Interface (MIDI) protocol. MIDI was a standardized data format for representing audio, which allowed game composers a simple way to create music and then provide programmers with the raw data dumps of that music. When CD-ROMs became popular in the early 1990s with the SEGA Saturn and Sony PlayStation, allowing for sampled audio, MIDI in games was for a large part abandoned in favor of more realistic but less dynamic music and sounds. Because the audio was not reliant on a sound card's synthesis,

CD-ROM technology ensured that composers and sound designers could not only know how the audio would sound on most consumer configurations but could also now record sound effects, live instruments, vocals, and in-game dialogue. Most consoles still continued to offer MIDI support with dedicated sound chips.

The Nintendo 64 surpassed the PlayStation in technical capabilities in many respects. The main processor controlled the audio and was capable of producing 16-bit stereo sound at a slightly higher sample rate than CD quality (48 MHz). Digital signal processing (DSP) filters and effects, such as chorus, panning, and reverb, could also be implemented in the internal CPU, or in the software, in real time. Some games supported surround sound, and this was further enhanced by the third-party add-on release of the RumbleFx 3D Sound Amplifier, a device that could help to mimic surround sound on a stereo system. This surround capability was expanded on by the release of the Sony PlayStation 2 (PS2) in 2000, which supported surround sound standards AC3, DTS, and Dolby Digital, offering up to eight separate speaker channels. However, limitations still meant that sound quality had to be compressed to save space, with the result being that cutscene sequences typically had high-quality full surround sound, but when the player began to use other resources requiring real-time processing, the music and sound took second place and often dropped down to two-channel stereo.

Sound capabilities continue to increase in terms of access to RAM, 3-D surround technologies, DSP effects, and simultaneous audio channels. Increasingly, full

orchestras are used for recording game music, and ongoing experimentation with algorithmically generative or procedural audio continues to expand the options that composers and sound designers have to create realistic yet dynamic audio.

South Africa

Before the 1990s, only some hobbyist development was happening in South Africa, including the game *Blastar* (1984) for the Commodore VIC-20 by Elon Musk, of Tesla and SpaceX fame, who at the time lived in Pretoria.

Celestial Games was established in 1994 in Johannesburg by Nick McKenzie and Travis Bulford, and their first game,

Toxic Bunny (1996) for PC, was published by local distributor Vision Software. The game shipped 150,000 units, allowing Celestial to work on a more ambitious title, the action role-playing game (RPG) *The Tainted* (2000), which sold about 5,000 units; however, the income was not enough to keep the company going, and it shut its doors in 2001. Celestial later reopened and produced an HD remaster of *Toxic Bunny* (2012) and is currently working on the *Table Realms* platform.

The late 1990s saw the arrival and growth of the SAGamedev.com website, a community site that allowed South African hobbyist game developers to share and showcase their work, with a particular focus on technology development.

In 1999, Dan Wagner, a South African-born graduate of Digipen Academy, founded I-Imagine Interactive in Johannesburg. He hired a number of U.S., Canadian, and South African developers to work for the company in Johannesburg on the driving game *Chase: Hollywood Stunt Driver* (2002). I-Imagine was selected for the Xbox Incubator Program, and this helped *Chase* launch as an Xbox exclusive, published by Bam!, scoring 60 on Metacritic. I-Imagine's next titles were the PSP-exclusive *Final Armada* (2007), published by Virgin Play S.A. in Spain, and the trivia game *Football Genius* (2009) for Xbox 360 and PS3, with a Metacritic score of 61. I-Imagine ported a version of the game to iPhone in 2010.

After leaving I-Imagine, Matt Benic and Chris Tsimogiannis started Smallfry Mobile, a Johannesburg-based studio focused on J2ME titles. During 2004–7, the studio released a number of titles,

including the shooting game *Abyss*, puzzle games *BrickLink* and *PlikPla*, and typing game *BBQT*, before closing.

Runestorm, a studio based in Kwa-zulu-Natal, was formed in 2005 by brothers Nolan, Arn, and Logan Richert to work on *Unreal Tournament* mods. Their first commercial title, *Rooks Keep* (2013), a melee arena combat game, launched on Steam. The highly successful simulation satire title *Viscera Cleanup Detail* (2015) entered early access the following year. Both titles were self-published.

Former I-Imagine staffer Diorgo Jonkers started Gojo Entertainment in 2005 in Grahamstown. Gojo's first game, the platformer *Demolish* (2001), launched for PC and was ported to J2ME devices in 2004. Games released under the Gojo banner included *Painty* (2006, PC), *Skel-eton Coins* (2007, PC), *Pure Fun Soccer* (2012, iOS) and *Love Dodge* (2013, iOS). Gojo has also released assets on the Unity Asset Store.

In 2005, a new local development community, Game.Dev, was established as a subsection of the forums of the then successful local *NAG Magazine*, which primarily focused on game design rather than technology and was largely driven by local enthusiast Danny Day. Through themed competitions and accompanying segments in *NAG*, this community helped to grow South Africa's hobbyist community. It was augmented in 2006 with a regular online game development magazine, *Dev.Mag*.

Luke Lamothe, an I-Imagine veteran, started Luma Arcade in Johannesburg in partnership with the film effects company Luma Animation in 2007. The studio released advergames, including *Mini 37*, *Nokia Navigate around Town*, and

Ultimate Grand Prix Drive for J2ME phones. A number of early commercial mobile titles for J2ME handsets included *Bun & Bunee: Island Hop*, and *Fashion Empire*. Garage Games published the online racing game *REV* as well as the iOS puzzle games *Marble Blast Ultra* and *Flipt*. The action RPG *The Harvest* (2010) was published for Windows Phone by Microsoft as a platform showcase title. The iOS and J2ME puzzle title *Monty Python's Cow Tossing* was published by Zed Group. Graphical showcase *Bladeslinger* (2012) was an action-adventure title for iOS and Android published by Kerosene games. After *Bladeslinger's* release, Luma Arcade was absorbed into the San Francisco-based Beyond Games, though part of the team remains in South Africa and works on mobile titles.

In 2007, RetroEpic was formed in Cape Town by Niki and Keith Boshoff. The company released the turn-based puzzle game *A Day in the Woods* (2011, PC), and later ported it to mobile platforms. It provided technical services on third-party titles, including *Every Single Soldiers' Afghanistan '11* (2017) and *Carrier Deck* (2017). Other third-party titles included *Sharkie* (2012, iOS and Android), ZAC's *Batting Academy* (2014, iOS and Android), *Scorch Runner* (2015, iOS and Android), *Jungle Beat* (2015, iOS and Android), and a digital version of *Flashpoint: Fire Rescue* (2018), a game from the company Indie Boards and Cards.

Former I-Imagine staffers Henk Bernhardt and Benjamin Duk started Open-Reset in 2007 and released a UDK demo of the platformer *Bounty Arms* (2011), which was completed in Unity for iOS and Android and published by Kerosene Games in 2012.

Cape Town-based indie studio QCF Design was started by Danny Day and Marc Luck in 2008. Its rogue-like *Spacehack* earned a place in the top 20 of the 2008 Dream-Build-Play competition, and the later rogue-like *Desktop Dungeons* (2013), designed by Rodain Joubert, won an award for Excellence in Design at the 2011 Independent Games Festival. The game launched to critical acclaim on Steam, followed later by iOS and Android ports. Its arcade title *Drawkanoid* (2019, PC) won the 2019 Nordic Game Discovery Contest. The studio has additionally created a number of educational and advergames products.

Durban-based studio Lighthouse Games, founded in 2009 by Neil Jones and Edward Dennenkamp, has released many Xbox 360 titles, including *Fireplace* (2008; prior to formation), *myFishtank* (2009), *Avatar Rockets* (2009), *Avatar Cannon* (2010), *Super Tricky* (2010), *Tiny Tim's Tremendous Tank* (2010), *Prank Call* (2011), *Avatar Onslaught* (2011), *Monster Talk* (2011), *Trigger Finger* (2011), *Flirt* (2011), *Avatar Onslaught Blizzard* (2011), *Avatar Onslaught 2* (2012), *Avatar Deathmatch* (2012), *Comedy Night* (2012), *Prank Call 2* (2012), *Shark Attack Deathmatch* (2012), and *Avatar Deathmatch City* (2012). For Windows Phone, it released *Torchbear* (2011), *Greed City* (2013), *Zombie Warfare* (2014), *Russian Roulette* (2014), and *Tod the Talking Toad* (2015). Additionally, it released *Shark Attack Deathmatch 2* (2015, Steam), *Comedy Night* (2017, Steam), and *Challenge Stars* (2018, Android). The studio relocated to London in 2017.

Canadian immigrant Steve McIvor founded Tasty Poison in Cape Town in 2010 and released *Pocket RPG* (2011,

Android and iOS), the puzzle game *Dig!* (2013, iOS, Android, and Ouya), and the multiplayer shooter *Neon Shadow* (2015). Tasty Poison also worked on a number of advergames and other partner projects.

Rising Phoenix Games was started by Rodney Sloan in Pretoria in 2010. While the company's main focus is tabletop RPGs, it has also released web games, including the text adventure *Rusty Blade* (2017) and the interactive visual novel *Dark Lily* (2017).

In 2011, Jason Reid returned to South Africa after stints at Disney and Eidos to start the augmented reality (AR)-focused studio Fuzzy Logic in George with cofounder Brad Hogan. The studio released a number of mobile titles, many of which are AR focused. Most of these were self-published: *Soccer Moves* (2013), *Secrets & Treasure* (2014), *Sketch Happens* (2018), and *#Tapgym* (2018). *Skylanders Collection Vault* (2014) was published by Activision.

Sea Monster, started in Cape Town in 2011 by Glenn Gillis and Wynand Groenewald, has established itself as a leading developer of serious games and advergames products. Among these, in 2016, it self-published the first in its acclaimed *Super Animals Augmented Reality* series, which attracted over 1.5 million downloads.

Duncan Bell started the Johannesburg studio Red Dot Lab in 2011. It self-published the action game *Blazin' Aces* (2014) and mostly worked on free titles, including *Skadonk Showdown*. It also has a number of assets in the Unity Asset store and offers contract work to other local studios.

Free Lives, probably South Africa's best-known studio, was founded in Cape Town by Evan Greenwood in 2011. Its

first game, *Broforce* (2015), was published to Steam by Devolver Digital after three years of open development, including time in Steam's Greenlight program. It was later ported to the PlayStation 4 (PS4) and Switch. *Broforce* is a side-scrolling run-and-gun platformer that features destructible environments and parodies of well-known action heroes. *Expendabros* (2014), a game made in partnership with Lionsgate for cross-promotional purposes, has the gameplay of *Broforce* but featured characters from the film *The Expendables 3* (2014). Finally, *Gorn* (2017) is a VR gladiator simulator released to Early Access on Steam by Devolver Digital.

In 2012, a new organization arose out of the success of the Game.Dev community and the need for better community organization and representation of the industry in general; Make Games South Africa (MGSA) had a web presence at makegamesa.com and took an active part in the running of local meetups. The initiative was spearheaded by community veterans Danny Day, Hanli Geyser, Jonathan Hau-Yoon, Andre Odendaal, and Ernest Young, along with intellectual property lawyer Nick Hall, who had begun to represent a number of local studios. The same year, the SAGamedev community site was taken down by its owners after disagreements with community members on what its role and focus should be.

Other studios appeared in 2012. Luke Lamothe, formerly of Luma Arcade, formed 24 Bit Games, a technical game development services company that offered porting, optimization, and other programming services to high-profile international clients such as Disney, Devolver Digital, and Unity as well as for

many local studios. Pieter Loubser started Stellenbosch-based studio Inventit, which released a multiplayer strategy title, *Farm Wars* (2012), for the chat-and-app service Mxit. Durban-based indie studio Rogue Moon Studios was started by Gareth Fouche to make strategy games, including the cyberpunk-themed *CCG System Crash* (2016).

The year 2013 saw more industry expansion. Herman Tulleken and Jonathan Bailey started Gamelogic in Johannesburg, focusing on Unity Store code assets, including grids, words, colors, abstract strategy, and extensions; in 2014, Gamelogic got accepted into Startup Chile and relocated there. Simon Spreckley, David Moffatt, and Larry Katz started Thoopid in Cape Town, self-publishing *Snailboy: An Epic Adventure* (2013), *Tap the Coin* (2014), and *Snailboy: Rise of Hermitron* (2017). Every Single Soldier, a studio focused on abstract strategy titles, was started in Cape Town by Johan Nagel to realize his vision of a game that realistically represented the importance of the psychological aspects of warfare; *Vietnam '65* (2015), *Afghanistan '11* (2017), and *Carrier Deck* (2017) were all published by Slitherine. The Johannesburg studio Skobbejak Games was started by Tiaan Gerber and Alexander Ehlers, who self-published the first-person horror *Vapour* (2015), the first-person platformer *'n Verlore Verstand* (2016), the adventure game *Tyd wag vir Niemand* (2017), and the first-person shooter (FPS) *Geeste* (2018).

The Brotherhood was started in 2013 in Johannesburg by brothers Christopher and Nicolas Bischoff to make high fidelity adventure games. It relocated to Cape Town in 2016. After a successful Kickstarter, *STASIS* (2013), its highly

acclaimed first sci-fi horror-themed game, was self-published on PC in August 2015 and was followed by the similarly themed *CAYNE* in 2017. Originally formed in Durban by Matt Cavanagh in 2013 to create Windows Phone applications, Rogue Code went on to self-publish its top-down shooter *Vicious Attack Llama Apocalypse* on Xbox One and Steam in 2018.

David Mulder started Red Splat Games in 2014 in Port Elizabeth. The studio has since moved a few times, to Cape Town in 2015 and to Cradock in 2016. It self-published the puzzle game *Grey Matters* and tower defense title *Defender of Light* for Android in 2014. Its focus then shifted to Steam, on which it has published a number of titles, including the platformers *Eron* (2015) and *Hot-Floor* (2018); the racing game *Eight Mini Racers* (2016); the casual games *Vector Velocity* (2017), *Butterfly Moment* (2017), and *Not without My Poop* (2018); the puzzle games *Prime Shift* (2017) and *Paradox Wrench* (2018); and the shooting games *Smithy* (2016), *Burst* (2016), *Hover Hazard* (2016), *Bits n Bullets* (2017), *222* (2019), and *BUTCHERBOX* (2019).

Team Lazerbeam was started in Cape Town by Jason Sutherland, Richard Pieterse, and Ben Rausch in 2014. Its list of games, all self-published on PC, includes the simulation game *Bionic Bliss* (2014), the adventure game *Pizza Quest* (2015), and the dating simulation games *Wrestling with Emotions* (2016), *Dress to Express Dancing Success* (2016), *Snow Cones* (2015), and *Snow Cones 2* (2017). That same year, Twoplus Games was started in Johannesburg by Steven Tu. Its first game, the endless runner *Dead Run*, launched on iOS, Android, and Windows Phone in 2015. Francois van

Niekerk, Leon van Niekerk and Hilgard Bell founded Clockwork Acorn in 2014. Its turn-based puzzler *Monsters & Medicine* was originally released in 2014 and was rereleased on Steam with an art update in 2017. *Luminare*, another puzzle game, was released in 2015 to mobile platforms.

In 2015, Cukia Kimani and Ben Myres started Nyamakop in Johannesburg. The studio's first game, *Semblance*, a puzzle platformer, was launched to Steam and Switch with publishers Good Shepard Entertainment in 2018. Also founded in 2015 was Orange Spice Games, started by Neil Moore, which has since self-published three puzzle games for Android, Windows Phone, and Windows Desktop: *Wordfix* (2016), *Sudomatik Mini Killer Sudoku* (2016; also released to Facebook), and *Ornamental Christmas Memory Game* (2016–19). Geoff Burrows started Zero Degrees Games in Johannesburg in 2015. The studio's first game, the first-person adventure *Among the Innocent: A Stricken Tale*, was self-published to Steam in 2017. In 2015, Alwynd Dippenaar self-published two action adventure titles, *FishGibble* and *Heroes Foe*, for Windows PC, Android, and iOS. In 2018, he started the company Goofish Game Studios in Johannesburg to release *FishGibble 2* for Windows PC, this time on Steam.

In 2016, Cape Town-based Balisti Studios was started as a spin-off from the animation studio Triggerfish Animation. Balisti offers cinematic and other art services to international game development clients. The projects it has contributed to include Bioware's *Anthem* (2019), Pixel Toy's *Warhammer Age of Sigmar: Realm War* (2018), Disney's *Baby Doc McStuffins* (2017), Nordeus's *Spellsouls: Duel of*

Legends (2017), and other work for Unity. Output Games was started in 2016 in Johannesburg by Tyron Janse van Vuuren and Shayne Mann. The studio's puzzle-platformer *ECHOPLEX* was released on Steam in 2018.

Also in 2016, as it became apparent that MGSA could not simultaneously play the roles of community organization and industry representative body, Independent Entertainment South Africa was formed to focus on industry representation and advocacy. MGSA retained its role as South Africa's central community organization for professional, hobbyist, and student game developers. Under the leadership of Nick Hall, IESA has since facilitated numerous trade missions, represented industry interests in issues ranging from age ratings to funding, and organized the highly successful first annual Make Games Africa B2B conference in Cape Town in 2018.

In 2017, Sunelda van Zyl and Werner Olivier started PaleBlue XYZ in Pretoria. Its education puzzle game *Number Hunt* was self-published for PC VR in 2018. Marc Luck started Tangled Mess in 2017, after he and fellow QCF veterans Dorianne Dutrieux and Robbie Fraser created *Volantia* at the Stugan Games Accelerator. The game launched on Steam in 2018.

More new studios appeared in 2018. The Johannesburg studio Hubblegum was started by Ben Crooks and Andrea Hayes; its casual narrative game *Helping Hand* (codesigned with Aiden Cammell), about communicating by only using one-handed gestures, was self-published to Steam in 2018. Stephen Bester, Johnny Saleh, and Johan van Staden started Deep Space Digital and self-published its first game, *Spider Flush*, an infinite

runner for Android and IOS. PAIN Games was started by Jaco Mostert, Raymond Beets, Karel Swanepoel, and Nico Kopf in Centurion, and its first game, the puzzle platformer *Gumstein: The Awakening*, was self-published to Steam in 2019.

With a growing number of studios and connections to the global industry, it seems that the South African video game industry will continue to flourish in the years ahead.

South Korea

Online gaming has been identified by the South Korean government as a national core industry to support. With the government’s strong backing, Korean online games have become one of the most globalized and lucrative sectors in Korean cultural industry. More than half of the South Korean population are online gamers. In the whole world, one can rarely find people more enthusiastic, committed, and professional about online gaming.

The success of Korean online games is no accident, and everything has worked out according to an official plan. South Korea used to be a consumption market for foreign games and has only become a major game exporter since about 2000. Until the ban on Japanese cultural products was overturned in 1998, Japanese games were popular in the Korea underground. Around this time, the Korean government promulgated the policy of building Korea into a cultural empire by providing investment and logistics support as well as policy and legal backup. Because of the problems of piracy and the dominance of Japanese games in most

existing platforms, the Korean government and game manufacturers decided to focus on online game development.

In 1999, the Korean government established the Korea Game Development and Promotion Institute (now renamed the Korea Game Industry Agency), a semiofficial organization to provide strategic planning and support for the Korean game industry. It is actively involved in professional training, direct investment, technological development, game design, purchase of equipment, and overseas promotion.

The pace of Korean online game development has been astonishing. In less than a decade, South Korea has become an online game giant, exporting its products to every corner of the world. South Korea is itself a large consumption market for its own online games. The playing of online games is now a national pastime, with 35 percent of the entire population participating in online games. *Crazyracing Kart rider* (2004), an online car racing game, has been patronized by one-third of the entire population. Online game centers (called PC Bangs, in Korea) are everywhere, and their number is estimated at around thirty thousand, about six times more than that of convenience stores

Korean online games such as *Legend of Mir 2* (2001), *Lineage* (1998), and *Ragnarok Online* (2001) created a commotion in Asia. In July 2002, there were 500,000 simultaneous users playing *Legend of Mir 2*, and in 2004, *Lineage* had 350,000 simultaneous users at its peak. The game has 6 million users in Korea and more than 10 million users in the world. From 2008 to 2013, the Korean game market achieved double-digit growth. From 2014 onward, the market share of Korean games in Korea began to drop, as many

Korean players have turned to play imported games such as *League of Legends* (2009), *Diablo III* (2012), and *FIFA Online 3* (2012).

The Korean government and game manufacturers have made online gaming a respectable profession. Game tournaments with enormous cash awards are organized to nourish professional game players in South Korea and to attract top-tier players from all over the world. Large-scale game tournaments are usually held in a stadium or concert hall. The most important one is World Cyber Games (WCG), the world's largest esports tournament, which has been held annually since 2000. In gaming circles, the winner of WCG is comparable to an Olympic gold medalist.

Professional game players are licensed by the Ministry of Culture and Tourism. National team members are national heroes and public icons. Seo Ji-hoon, the former WCG champion, is one such example; more than seven hundred thousand people have joined his fan club, outnumbering the fans of his counterparts in the singing or acting business. He makes appearances on TV programs and commercials as well as at public functions and was invited to visit Taiwan to see his fans there. To further enhance the status of professional game players, the Korean government revised its ordinances in 2006 to reduce or exempt them from national service. Nowadays, esports are big in South Korea and are ranked the third most popular youth sports, after soccer and baseball. "Faker" (real name: Lee Sang-hyeok), a top player of *League of Legends*, is a national icon. He is referred to as the "Michael Jordan of esports."

The Korean model, which puts emphasis on the role of government, has had a

very strong impact in Asia. Mainland China, for instance, is adopting the same model to develop its online game industry. Today, South Korea is facing competition from new online game powers, such as Mainland China, Taiwan, the United States, and Japan. South Korea's market share overseas is shrinking; its market share in the online game market of Mainland China has dropped from 70 percent to 30 percent and in Taiwan from 80 percent to 40 percent. The future of Korean online games has challenges ahead.

Space (Narrative)

Narrative space is an academic concept within video game studies for researching game space. The visual space (see Space [Visual]) in combination with narrative elements forms the narrative space. These

narrative elements can be divided into three categories: narrative sequences, exploration, and mapping.

Narrative sequences form the main storyline of a game. This can be done in various ways, for example, through the use of cutscenes, dialogue, and quests. A *cutscene* is an animation that is meant to convey certain information to the player. It can be used as a tool to develop the plot of the main narrative of the game. Cutscenes mean a break in gameplay, whereas a *dialogue* forms a narrative sequence that can be used during gameplay. In *Grand Theft Auto IV* (2008), for example, players can still control their avatar while listening to dialogue that provides background information on the main storyline. Quests, as embedded in *World of Warcraft (WoW)* [2004], offer another way of presenting narrative information to players. A *quest* is a task given to a player who receives a reward upon finishing it successfully. Quests often form chains, meaning players start with one quest that, upon completion, is followed by another quest, thus forming storylines. Quests can also be used to guide players through the narrative of the game.

Exploration of a game's visual space by the player also forms an important narrative element of the narrative space. At the start of any game, players need to explore the space to learn how to progress and function within the world of the game. Exploration then entails the discovery of the game world but also the navigation of space. The ability to navigate through a space can create dramatic experiences (Murray 1998). A space that a player has visited then becomes a space where narrative events have taken place. Previous to the players' interference, the space could be defined as a *map*—an objectified

spatial relation—and after the players' interference, it can be defined as a *tour* that represents the personalized journey through space (Newman 2004). An example of games in which exploration forms the narrative space can be found in shooting games such as *DOOM* (1993). In shooters, the game space is usually structured like a maze, wherein players have to navigate their way from one place to another. During their journey, they explore the space and create a narrative tour.

Players construct a mental map of the game while they piece together the narrative sequences and explore the space (Jenkins 2006). This mental map changes and adapts every time players come upon new information, and players consequently act on this mental map. The game space can then provide narrative descriptors (Salen and Zimmerman 2004) that will assist the players' process of mapping. Narrative descriptors are objects visually present within the game world that give a narrative explanation. Through their use, narrative information does not have to be given directly in exposition because players can draw their own conclusions and obtain information indirectly from the narrative space. Examples of the use of such narrative descriptors can be found in *Myst* (1993). In this game, players enter what appears to be an uninhabited game world in which they will have to gather clues to solve puzzles. At most locations, players can get a sense of what took place by reading the narrative descriptors, such as abandoned weapons that explain the intentions of the owners. Players then use the information from the narrative descriptors to adjust their mental map accordingly to function within the game world—for instance, by considering the

weapons' owners as evil and performing actions against them.

Narrative sequences, exploration, and mapping are also interconnected. A game can open with a cutscene, and through this narrative sequence, the setting of the game is explained, from which players can base their process of mapping. Players then act on this map by exploring the space, during which they stumble on new narrative sequences that influence the mental map. The way narrative space is constructed often depends on the type of game. In first-person shooting games, the emphasis usually lies on the exploration of space, whereas in many role-playing games (RPGs), narrative sequences can predominate. Almost all types of games require mapping by the players.

In game design, space—and thus narrative space—plays an important role in the construction of the game world and the players' experience. Narrative space can give meaning to players' actions and provide them with more immersion and pleasure. Narrative space is often implicitly defined when mentioned in academic writing and is used in various ways that depend on the academic discipline using it; ludology, for example, focuses more on gameplay than narrative and thus would be more likely to examine exploration than narrative sequences. Even though there are a range of implicit concepts of narrative space used, there has been relatively little academic debate about the topic.

Space (Visual)

Because of their nature as visual media, video games always involve some sort of graphics, which are usually used to represent some form of visual space in which the games' events take place (see also Space [Narrative]) and may also include nondiegetic spaces such as high score screens or game instructions. Space in video games is different from that in film or television because of the interactivity available to the player, who is often able to determine which spaces are seen on-screen by moving the player character and its point of view. An examination of game space, then, should consider how spaces are represented, their dimensionality, their connectivity, and whether they require navigation.

At any given point in a game, its spaces are either on-screen or off-screen. On-screen spaces are those visible to the player (representing the player character's point of view or a third-person perspective of the player character) and are usually those in which players are active. Off-screen space is often implied by visible spaces that move on- and off-screen (as in games with scrolling); off-screen

sounds, events, or information (e.g., in the radar scope in *Battlezone* [1980]); or with maps that reveal areas that the player has not yet seen. As in film, off-screen space is important in establishing a game world that is much larger than what appears on the screen, encouraging speculation and exploration.

Dimensionality refers to the fundamental structure of the space and may range from simple two-dimensional spaces that consist of a single game screen, like that of Atari's *Tank!* (1974); to so-called two-and-a-half-dimensional spaces made up of layers of independent but overlapping planes, as in *Super Mario Bros.* (1985); to games set in a computationally true three-dimensional space rendered in real time as the player character moves through it, as in *Tomb Raider* (1996) and *Halo 2* (2004). Some games simulate a third dimension through pre-rendered graphics (such as those using an axonometric perspective in *Zaxxon* [1982] and *SimCity 2000* [1993] or the first-person perspective imagery in *Myst* [1993]), lines or objects that suggest a first-person perspective (as in *Night Driver* [1976] and *Speed Freak* [1978]), scaling sprites that imply z-axis depth (as in *Pole Position* [1982] or *Space Harrier* [1985]), or objects redrawn in such a way that they appear to be turning in space (as in *Nebulus* [1987]). Other games using full-motion video (FMV) clips look three dimensional, such as *Star Trek: Borg* (1996), but as pre-rendered graphics, they allow little or no interaction.

Games can also have spaces of mixed dimensionality. Different levels of the same game can have different dimensionality; for example, in the three-stage shooting game *Tac/Scan* (1982), the first stage is two dimensional, similar to

games such as *Galaxian* (1979) and *Space Invaders* (1978), but its second stage, "3-D Armada Attack," has players firing into the screen instead of up or down the screen. Mixed dimensionality can occur within a level as well, as in *DOOM* (1993) and *Super Paper Mario* (2007), in which two-dimensional characters and objects move through a three-dimensional space. Games can even play with the notion of dimensionality, as in *Echochrome* (2008), in which players rotate objects in three dimensions while reading them in two dimensions for the connections that the player character uses to make sense.

The spaces of games can also be non-Euclidean in nature. Even the simple, single-screen wraparound space of *Asteroids* (1979) represents the surface of a non-Euclidean 2-torus. Other games link screens in such a way as to make their space non-Euclidean (e.g., *Adventure* [1979]), and others are designed in such a way that two or more different spaces seem to occupy the same space, depending on how they are entered, as in *Duke Nukem* (1996) and *levelHead* (2007). Such games demonstrate the malleability of space available to the video game designer, who can connect spaces in ways that are nonintuitive and physically impossible.

Whether spaces are Euclidean depends on how they are connected to themselves or other spaces, and connectivity determines how spaces are structured. Connections between spaces can be indicated by the ability to move from one space to another, the ability to look into another adjacent space (as through a window), or by implication through the arrangement of spaces as on a map. Players often need to be able to identify which spaces are navigable by learning how to move and

testing areas to see whether they can be entered. Even spaces a player character cannot enter can be important because the player may be able to influence events there—for example, by shooting (as in *Space Invaders*, where the player character is limited to moving across the bottom of the screen).

Finally, game spaces can be overlaid over physical spaces, as in games involving augmented reality (AR), such as *Ghostwire* (2008) or *Sky Siege* (2009), which position game elements virtually in the space around the player, who must turn around and use a mobile device as a window to see what is occurring in the game. Pattern recognition and motion detection software will allow more AR games to become available on systems with built-in cameras, such as the Nintendo DSi, the PlayStation Move, and the Kinect for the Microsoft Xbox 360.

Space, or the implication of space, must precede temporality and narrative because both require events, and events require space. Thus, our awareness of space in a game comes before the temporal and narrative aspects (unless these are acquired through materials outside of the game itself, as is often the case). Spatial design usually gives the player some sense of the temporal and narrative structures of a game as well. These can be expanded through both innovative software and hardware designs that experiment with the representation, manipulation, and navigation of space. Questions regarding the design of video game spaces, how those spaces are connected, and how they are experienced are essential to video game studies and the study of the human experience of spatial representations in general.

Space Invaders

Designed and programmed by engineer Toshihiro Nishikado, *Space Invaders* (1978) was the first arcade game released by Taito, the popular pachinko machine manufacturer. Interestingly, *Space Invaders* originated from an evaluation tool to test computer programmers' skill with hexadecimal mathematics and was inspired by Nishikado's love for the film *Star Wars* (1977), H. G. Wells's novel *The War of the Worlds* (1898) and the subsequent 1938 Orson Welles radio adaption, and Apple cofounders Steve Wozniak and Steve Jobs's *Breakout* (1976) game published by Atari. Because it was politically incorrect to harm humans in games at the time, the army onslaught was

A screenshot from the original version of Taito's *Space Invaders*, released in the arcade in 1978. (Courtesy of Mark J. P. Wolf)

replaced with alien aggressors looking for global domination. Despite a lukewarm response from company executives, the game emerged and was released to little fanfare, at least initially.

After a few months, however, *Space Invaders* became so popular in Japan that it caused a shortage of the 100 yen coin—the coin needed to play the game. This shortage affected several other aspects of Japanese life, including the heavy disruption of the primary form of transportation, the subway. *Space Invaders* had brought Japan to its knees, and the government was literally forced to quadruple the production of the yen coin to meet the new demand.

Because of its intensifying popularity, entire arcades were opened in Japan specifically for *Space Invaders*, many of

which held dozens of *Space Invaders* games and no others. As hysteria concerning the game mounted, a number of shop owners abandoned their goods and converted their stores to video arcades, some complete with booming audio systems broadcasting the thumping march of the invaders into the streets. With the ever-growing demand, other venues started hosting coin-operated machines, and *Space Invaders* had found a habitat everywhere—from pizza parlors, restaurants, and bars to drugstores, laundry mats, roller rinks, grocery stores, and even such unlikely locales as funeral homes.

Before *Space Invaders*, a good run for a coin-op release was a few thousand machines. For *Space Invaders*, a staggering five hundred thousand-plus coin-op

machines were sold worldwide in the first year, 70 percent of which remained in Japan. In time, more than one hundred thousand *Space Invaders* games had been distributed, and more than three hundred thousand were built (if counterfeit versions are included). Billions of coins were pumped into the machines for the first few years, amassing more than \$500 million in revenue for Taito, making the entire entertainment industry sit up and take notice.

A large portion of these coins came from teenagers eager to play. Unfortunately, many of them engaged in theft, robbery, and panhandling to acquire coins to get their fix. As a result, these inappropriate actions led to the first of what would become a trend of public outcries against the video game industry. In the United States, groups of concerned parents and government organizations that feared games tainted the minds of schoolchildren worked their case to ban the machines all the way up to the U.S. Supreme Court (DeMaria and Wilson 2002, 46).

The concept behind *Space Invaders* was simple in design; it was an adaptation of carnival shooting galleries. The player would guide a laser cannon located on the bottom of the screen from left to right to shoot down wave after wave of marching alien raiders. The laser cannon could hide behind four bunkers that served as obstructions, defending the laser cannon from the aliens' rays and bombs. The bunkers, and the player-controlled laser cannon, would eventually be destroyed by the relentless alien invasion that slowly advanced from the top of the screen to the bottom. On occasion, an alien spaceship, which could be shot down for

bonus points, would fly across the top of the screen.

One factor that added to the hopeless tension created while playing the game was the increasing speed of the game as more invaders were destroyed. The aliens moved faster and faster, and the audio, reminiscent of the thumping sound of a beating heart, became more rapid during their descent. Although many identify this rapid increase as one of the greatest game design scenarios of all time, it was a result of hardware technicalities and not of intentional devising or fancy programming; the processor was able to update the screen more frequently as the number of enemies decreased. This resulted in the ramped-up speed of the aliens and the soundtrack.

Midway licensed *Space Invaders* from Taito and released the game in the United States. Although it did not create a quarter shortage, it was unparalleled in popularity. In a good location, the game could pay for itself in less than a month, placing video games among the most lucrative equipment a merchant could possess.

Atari, the American company with a Japanese name, recognized the opportunity and licensed the game for release on the Atari VCS 2600 console. Whereas *PONG* (1972) was the first coin-op game to appear in the home in the form of a stand-alone unit, *Space Invaders* was the first video arcade game to be adapted to a home console on a physical interchangeable cartridge. The VCS release of *Space Invaders* was also historical because it was the first game to be licensed by another company and adapted for play on a home console. The VCS conversion also expanded on the coin-op version by offering 255 different

gameplay variations. Atari even focused its advertising budget and marketing efforts to sell *Space Invaders* instead of the VCS console itself. As a result, sales of the VCS spiked, and *Space Invaders* became the first “killer app” (a must-have application that causes many people to buy a new system).

The Atari VCS 2600 had been released in 1977, but it was not until 1980, when consumers purchased the console with an accompanying copy of *Space Invaders*, that Atari’s unit sales skyrocketed. The company began to empty its warehouse and the excess stock of four hundred thousand units (Herman 1994, 38). Demand had become so high that the VCS had to be rationed out to retailers, and manufacturing production had to be stepped up. In addition to the system sales, the game sales of Atari’s home version of *Space Invaders* grossed more than \$100 million for Atari (Santulli 2002, 72); Atari’s combined gross income reached \$415 million. As a result, Atari’s gross income more than doubled, leading its operating income to rocket to a third of its parent company, Warner Communications. This in turn caused the stock to rise 35 percent, resulting in Atari becoming the fastest-growing company in history (Herman 1994, 43).

The crude sprite graphics of *Space Invaders*, although simplistic by today’s standards, were groundbreaking at the time. The alien aggressors were the first characters to have individual animation while moving horizontally and vertically within the playing field. The creatures have also become icons for the industry and are widely recognized symbols of video gaming. *Space Invaders* is among the most influential video games ever created and took the world by storm,

contributing to a video game craze that continues to this day.

Spacewar!

Spacewar! is a two-player space combat game originally created for the DEC PDP-1 minicomputer. Written during the winter of 1961–62 by a group of students at the Massachusetts Institute of Technology (MIT), it is one of the earliest known graphical computer games.

The game was first conceived by J. Martin Graetz, Stephen Russell, and Wayne Witanen. Strongly inspired by contemporary science fiction cinema and the space opera novels of E. E. Smith, it was designed as a “hack” to demonstrate the capabilities of the computer and its cathode-ray tube (CRT) screen. The development began in December 1961. The core program was written by Stephen Russell, with assistance from Robert Saunders. The initial version was completed by

February 1962. The game featured two spaceships, each with a limited supply of fuel and missiles. Using the switches on the computer's front panel to control rotation, thrust, and fire, the players attempted to destroy their opponent's ship. The combat was rendered across a randomly generated star field and limited to a single wraparound screen (objects traveling beyond the edges of the screen immediately reentered on the opposite side, at the same angle and velocity).

With basic gameplay in place, the hacker community thriving around the MIT computer lab immediately proceeded to introduce various modifications to the program. Peter Samson integrated his *Expensive Planetarium* into the game, replacing the random background with a realistic representation of the night sky as seen from Cambridge, Massachusetts. Dan Edwards introduced a central star with a surrounding gravity well, putting the ships at constant risk of being pulled in and destroyed. This increased the overall difficulty of the game and introduced an element of strategy into gameplay, as skilled players were able to use the gravitational pull to gain speed and perform advanced maneuvers. Finally, Graetz added the "hyperspace jump"—a chance to escape perilous situations by warping the ship to a random destination on the screen. The game was finalized by April 1962.

Although the earliest known attempts to create a computer game date back to the early 1950s, *Spacewar!* differs from these early attempts in two significant respects. The earlier efforts typically consisted of adapting traditional strategy games (such as chess, nim, or tic-tac-toe) for computer play and were tied to unique, custom-built machines. In contrast,

Spacewar! was designed from the ground up as a computer game and developed for a standardized hardware platform. With approximately fifty PDP-1 units in existence, the game was able to circulate (free of charge) between commercial and academic computing centers across the United States, gaining widespread popularity. It was also often modified and ported to other systems.

In the early 1970s, *Spacewar!* provided the template for the first coin-operated video game machines: *Galaxy Game* (1971), the earliest known coin-op video game, and *Computer Space* (1971), the first mass-produced arcade video game. The latter was designed by Nolan Bushnell and Ted Dabney, of Syzygy Engineering (incorporated the following year as Atari, Inc.), and distributed by Nutting Associates. The first arcade game utilizing vector graphics, Cinematronics' *Space Wars* (1977), was also a *Spacewar!* clone.

Spain

Although Spain's arcade game production during the 1970s amounted to only a

few electromechanical games, such as *Monza* (1977) and *Rally Cross* (1977), by the mid-1980s, Spanish software finally emerged from the cave. This splendid period (1983–89), known as “the golden age,” arose through the efforts of a group of young freelance programmers who founded and established, for the first time in Spain, a rich ensemble of software companies, including Opera Soft, Indescomp, Made in Spain, Dinamic, Topo Soft, Zigurat, and Aventuras AD. Most of their games were developed for the ZX Spectrum Sinclair, the MSX, and the Amstrand CPC. In terms of turnover, the Spanish video game industry became the second most important in Europe during the late 1980s, surpassed only by the United Kingdom. Spain’s international success was due to games such as Indescomp’s *Bugaboo* (1983), Topo Soft’s *Survivor* (1987), and Dinamic’s *Navy Moves* (1988).

The man who epitomized this golden age of Spanish software was Francisco “Paco” Menéndez (1965–99), unanimously considered the best Spanish video game creator. Menéndez began his creative career with the adventure game *Fred* (1983) at Indescomp and its sequel, *Sir Fred* (1986), at Made in Spain, the latter being one of the most innovative games of that year. For his first solo project, Menéndez conceived of an ambitious unauthorized adaptation of Umberto Eco’s celebrated novel *The Name of the Rose* (1980). Influenced by the games created by the Stamper brothers for *Ultimate* (especially *Knight Lore* [1984] and *Pentagram* [1986]), the game, eventually named *La Abadía del Crimen* (1988), is a deep and complex adventure, gorgeously designed by Menéndez and his collaborator, Juan Delcán. The game was a

milestone and is still considered the best Spanish video game ever created and one of the best games of all time for 8-bit machines.

In the 1990s, however, the Spanish video game industry collapsed. The companies were unable to adapt their production standards toward 16-bit platforms and succumbed. Only Dinamic survived, thanks to its *PC Futbol* franchise of football management simulation games, which were massively successful in Spain. Another exception was Gaelco, one of the few Spanish companies to emerge during the 1990s, which specialized in arcade games such as *Radical Bikers* (1998). Meanwhile, Bit Managers surfaced, developing a number of Infogrames titles, such as *Asterix & Obelix* (1995) for the Super Nintendo Entertainment System (SNES). The most successful Spanish game of the decade, however, was the remarkable *Commandos* (1999) by Pyro Studios, a real-time tactical game conceived by Gonzo Suárez, a distinguished and veteran creator who debuted in Opera Soft during the golden age (in fact, *Commandos* is explicitly dedicated to the memory of his friend Paco Menéndez, who passed away that same year).

After another lost decade (of the 2000s), two new Spanish companies now occupy the center of attention: Akaoni Studio, whose *Zombie Panic in Wonderland* (2010) for WiiWare became the most downloaded game in Japan, and Mercury Steam Studio, with its excellent *Castlevania: Lords of Shadow* (2010), published by Konami for the Microsoft Xbox 360 and the Sony PlayStation 3 (PS3) and supervised and supported by the great Hideo Kojima. Perhaps these

developments herald the coming of a new golden age.

Spector, Warren (1955–)

Warren Spector is a designer of role-playing games (RPGs) and computer games. He is notable for his work on the game *System Shock* (1994) and the *Ultima*, *Wing Commander*, *Thief*, and *Deus Ex* game franchises. He holds a bachelor’s degree in communications from Northwest University, Illinois, and a master’s in television, film, and radio from the University of Texas in Austin. Spector is married to fantasy writer Caroline L. Spector.

Spector began his professional career as a college professor. After teaching several undergraduate courses at the University of Texas and working a stint as an archivist at the Harry Ransom Center, he was offered a position at *Space Gamer Magazine*. In 1983, Spector was initially employed as an editor for the magazine but soon became the editor-in-chief of the company that owned the magazine, Steve Jackson Games. Spector began

creating RPGs for Steve Jackson Games, his most noteworthy title being *Toon* (1984), a cartoon RPG that parodies many of the conventions of more standardized tabletop RPGs.

In 1987, Spector was hired by TSR Inc., where he helped develop titles such as *Top Secret/S.I.* (1987) and *Spelljammer* (1989), a *Dungeons & Dragons* campaign that features an outer space environment. He also cowrote a novel for TSR titled *Double Agent: The Royal Pain/The Hollow Earth Affair* (1988).

Shortly after his work with TSR, Spector entered the computer game industry. Working with game developers Origin Systems, Looking Glass Studios, and Electronic Arts (EA), Spector helped develop many popular software titles. Spector’s game credits include *Wing Commander* (1990), *Wing Commander: The Secret Missions* (1990), *Ultima VI: The False Prophet* (1990), *Bad Blood* (1990), *Wing Commander II: Vengeance of the Kilrathi* (1991), *Wing Commander: The Secret Missions 2: Crusade* (1991), *Ultima: Worlds of Adventure 2: Martian Dreams* (1991), *Ultima Underworld: The Stygian Abyss* (1992), *ShadowCaster* (1993), *Ultima Underworld II: Labyrinth of Worlds* (1993), *Wing Commander Privateer: Righteous Fire* (1993), *Ultima VII: Part Two: Serpent Isle* (1993), *Ultima VII: Part Two: The Silver Seed* (1993), *Wings of Glory* (1993), *System Shock* (1994), *CyberMage: Darklight Awakening* (1995), *Crusader: No Remorse* (1995), and *Thief: The Dark Project* (1998). Spector is known to include cameos of his likeness in the games he works on.

In 1997, Spector founded the Austin branch of Ion Storm Inc. While there, he developed the titles *Deus Ex* (2000), *Deus Ex: Invisible War* (2003), and *Thief*:

Deadly Shadows (2004). He departed Ion Storm in 2004 to establish a new company, Junction Point Studios, which was acquired by Disney Interactive Studios in 2007. Spector's first project with Disney Interactive was *Epic Mickey* (2010), a steampunk-inspired title developed exclusively for the Nintendo Wii. This was followed by a sequel, *Epic Mickey 2: The Power of Two*, in 2012. In 2013, Junction Point Studios was closed, and Spector departed Disney Interactive.

In 2016, Spector joined Otherside Entertainment, a studio founded by Looking Glass cofounder Paul Neurath. Spector currently heads the company's Austin, Texas, studio and has assisted with development on *Underworld Ascendant* (2018) and the upcoming *System Shock 3*.

Speedruns

A speedrun is a popular method of game replay in which the goal is to achieve the quickest possible completion. While some categories focus on completing 100 percent of a game's content, others have different objectives: finishing the game with minimal collecting of items, using specific characters, or using bugs in the game to reach an end state far more quickly than the developer intended. Speedruns emerged from gaming communities as alternative modes of

competitive play but have evolved to include cooperative modes in which players work together, sometimes with multiple players on a single controller.

The rapid replay is meant to showcase a player's skill and memorization of a game environment, proving gaming prowess through a record speed finish. This mode took place in some early gameplaying (e.g., *Quake* [1996]), but it is most visibly featured and shared on online video sites such as YouTube and Twitch with the help of recording software and software emulators. Speedrun races and tournaments are built on a competitive foundation: players are forced to make rapid decisions that are also safe enough to prevent any lost time to their rivals if mistakes are made. Beyond individual player status and community rivalry, speedruns reveal game mechanics and their software complexity, as the technique subverts intended game paths and gameplay.

With classic games, speedruns function without evolving artificial intelligence (AI) or programmed computer enemies and environments—both of which are outside early technical softwares' abilities—making memorization easier to achieve. Games relying on repetition rather than randomization allow players to replay for speed rather than experience. Skilled speedrun players analyze game environments and their memory while playing. As a result, they can frequently identify how player actions impact the random number generator of a given game, allowing for personal control over elements that seem difficult to account for otherwise. Randomizer modifications in video games (such as *The Legend of Zelda: A Link to the Past* [1991]) change the locations of

items, bosses, and entrances, requiring players to use their knowledge of a game's mechanics to solve an entirely distinct version of the game.

With more contemporary games, players begin performing speedruns shortly after a title's release, but must constantly adapt their gameplay to changes created by developers via software patches and updates. Overall, speedruns can expose the replayability of certain games as well as the inability of others to offer alternate replay experiences, depending on how quickly players can complete their speedruns. The speedrun replay creates an alternate path to game completion that is meant to act as a challenge. Therefore, the speedrun operates differently from other replay modes to preserve play while relaying game mechanics and strategies to fellow players.

Spirituality

Spirituality is a broad category that generally refers to the personal experience of a religious tradition or other sacred phenomenon. Put another way, spirituality tends to emphasize the subjective qualities—such as feeling, attitude, perception, and value—that arise from an encounter with the transcendent. In some cases, video games attempt

to simulate or facilitate a form of spiritual experience.

The interdisciplinary study of spirituality emerged as an academic pursuit throughout the twentieth century and into the twenty-first century. In 1902, William James suggested that religious (or spiritual) experience was heterogeneous, expressing itself in a rich variety of emotions and behaviors as a response to the mystical and transcendental. Later, Rudolf Otto described spiritual experience in terms of the "numinous"—a nonrational sense of fascination and awe, of solemnity and longing that manifests itself in an encounter with the "wholly other" (Otto [1923] 1958; cf. Jung 1938). In a 1999 meta-analysis, researchers suggested that spirituality could best be understood as the integration of traditional religious categories with personal and social phenomena (Zinnbauer, Pargament, and Scott 1999). Oman (2013) notes that, although spirituality is hard to define, multidisciplinary approaches to understanding spirituality seem to affirm a "search process" for the sacred, with an inherent capacity for self-transcendence on the part of the one who searches.

Interestingly, early technology theorists suppose that computer technology may foster an experience of self-transcendence. Norbert Wiener (1966) suggests that self-transcendence is a by-product of creating various forms of artificial life. Bruce Mazlish (1993, 195) concurs, suggesting that the quest for self-transcendence through the creation of computer technologies and simulated worlds appears to be "one of humanity's deepest aspirations." Michael Heim notes that virtual reality (VR) can set the stage for "an experience of the sublime or

awesome” (1993, 137). He links this experience with *eros*—“a drive to extend our finite being” and “to heighten the intensity of our lives” (87).

Some video game theorists and researchers suggest in passing that video games may be able to foster a form of spiritual experience. For example, James Paul Gee suggests that video games may be good for the “soul.” He identifies the soul with “our emotions and imagination” (Gee 2005, 7) and theorizes that video games possess the capacity to feed the soul with meaning and significance along the way to human growth and development (119). Edward Castronova argues that “synthetic worlds” present players with transcendent vistas that evoke a sense of longing, mediate a sense of sublimity, and inspire a sense of reverence (2005, 106–112; Castronova 2007, 206–207). Christopher Scholtz (2004, 2005) speculates that video games may evoke an experience of joy and fascination that compares favorably to spiritual experience. Kutter Callaway (2010) imagines that video game play through systems such as the Nintendo Wii may facilitate a form of experiential integration—sensual, somatic, affective, and holistic—that supports spiritual experience.

Richard Garriott’s *Ultima IV: Quest of the Avatar* (1985) stands as one of the earliest attempts at integrating spirituality with video game design. In *Ultima IV*, the player seeks moral perfection on a spiritual quest to save the world. In fact, “spirituality” is one of the eight virtues that the Avatar must contemplate and practice. Although Garriott remarks at one point that *Ultima IV*’s aims are philosophical, not religious (Addams 1990, 40–42), elsewhere he remarks that the

player is the “spiritual essence” of the avatar (Herz 1997, 157) and that spirituality, religion, morality, and ethics lend “credibility and completeness” to game worlds (Bub 2002).

Other historic examples exist in which video game designers experiment with in-game spirituality. Peter Molyneux designed *Populous* (1989)—an ancestor of many “god games” to come—as a playful simulation of divine-human relations. Wisdom Tree Games published a series of religious video games for the Nintendo Entertainment System (NES), including *Bible Adventures* (1991) and *Spiritual Warfare* (1992). Rand and Robyn Miller created *Myst* (1993) and its sequels as an aesthetic expression of their Christian faith and worldview (Swain 2010). The work of Tracy Fullerton (2005) at the Electronic Arts Game Innovation Lab at the University of Southern California seeks to construct a procedural rhetoric of spiritual perception—particularly contemplation and mystical experience. In contrast, the real-time strategy (RTS) game *Left Behind: Eternal Forces* (2006) attempts to construct a procedural rhetoric of spiritual indoctrination from a fundamentalist perspective.

Patrick Slattery ([1992] 1999, 2006) suggests that spiritual experience is often mediated through a proleptic moment—a moment in time when personal awareness of the past and future powerfully converge in the present, overwhelming the subject with insight and revelation. A few current video games effectively utilize the proleptic moment as a means of simulating and facilitating spiritual experience for the player. Drew Davidson’s *Well Played 1.0: Video Games, Value and Meaning* (2009) recounts a wide range of

autobiographical narratives in which players occasionally describe the power of in-game proleptic moments—moments when time, meaning, and contemplation converge. In this regard, the player narratives about *Mines of Minos* (1982), *Shadow of the Colossus* (2005), and *Passage* (2007) bear particular weight. The platform game *Braid* (2008) also structures a proleptic moment through its narrative and ludological qualities.

Some video game designers seek to incorporate mechanics, aesthetics, or the wisdom traditions of spirituality in video game play to facilitate meditation and relaxation. For example, *Journey to Wild Divine* (2003) uses biofeedback fingertip monitors to assist players into contemplative peace throughout gameplay, while *Guru Meditation* (2009) uses either the Amiga Joyboard or iPhone accelerometer to monitor “legitimate zen meditation” (Bogost 2009). The publisher Thatgamecompany designs games with visual and sound elements that inspire feelings of awe, wonder, and other heightened emotions often associated with spiritual experience: *fOw* (2006), *Flower* (2009), *Journey* (2012), and *Sky: Children of the Light* (2019). *Never Alone* (2014) mediates an immersive exploration of indigenous ecospirituality within the context of an Alaskan Inupiat wisdom tradition. In contrast, *That Dragon, Cancer* (2016) presents a humbling, existential experience of self-limitation in the face of unanswerable questions about human suffering within the context of a Christian wisdom tradition. As Douglas E. Cowan (2019) writes, “Like all forms of complex storytelling and storyworld creation, videogames are a way for us to engage with questions of meaning, purpose, identity, . . . teleology[,] . . . suffering, [and] justice—we have tended to call these *religious*

questions when they are more properly human questions” (107–108). Toys and games do not lie outside the scope of spiritual concern (Bado-Fralick and Sachs Norris 2010). To the contrary, they can act as material gateways to spiritual searches for meaning and self-transcendence.

Sports Games

Sports games are one of the most popular types of video game on the market. A *sports game* may be defined as a game attempting to simulate an activity akin to real world sport. Different sports games will simulate sport in different ways and in varying degrees of realism, but all sports games provide some approximation of sport to the players. Sports games have also played an important role in the history of video games.

HISTORY

Some consider a simulation loosely based on sport, Willy Higginbotham's *Tennis for Two* (1958), to be the very first video game. Like *Tennis for Two*, many of the oldest sports games enabled gamers to bring their experience of real-world sport to the simplistic graphics of these early games. Sport provided an easy way to make sense of blocky pixels bouncing around the screen. In 1966, Ralph Baer began creating a ping-pong-like game for use with a television, and he invented a hockey game for television one year later. In 1972, Nolan Bushnell adapted Baer's game into *PONG*, the first widely played sports game and video game, and many other imitations appeared in the home game market. Other early sports game titles included *World Cup Football* (1974), *Grand Track 10* (1974), and *Grand Track 20* (1974). Atari's *Football* (1978) was among the first games with two-way scrolling and helped popularize the trackball controller mechanism.

During the 1980s, sports games were released for home consoles, such as the Atari VCS 2600 and the Mattel Intellivision, and for computers, such as the

Commodore 64, Amiga, Apple II, and the IBM PC. Varying television-style camera angles debuted during this period with *World Series Baseball* (1982) for the Intellivision. In a push to make sports games more realistic, sports game developers struck licensing deals with professional athletes, teams, and sports organizations. Some sports game developers consulted coaches and placed them on their covers to promote and legitimize their games as viable simulations. Examples of these games include *Earl Weaver Baseball* (1987) and *John Madden Football* (1988) from Electronic Arts (EA).

In 1993, EA established a unit exclusively devoted to sports games, EA Sports. Since then, EA Sports has created and published some of the most successful video game franchises ever. These franchises include the *NBA Live* basketball series, the *FIFA* soccer series, the *NHL* hockey series, the *Tiger Woods PGA Golf* series, and, most famously, the *Madden Football* series. Although other sports game developers had created games stressing realistic statistics, player physics, and graphics, EA Sports oriented its entire marketing and development focus around a commitment to realism in every area of its simulations. EA Sports also began the practice of releasing a new version of a sports game with the opening of each real-world sports season. Over the course of its history, EA Sports has published games based on auto racing, baseball, rugby, cricket, Australian rules football, boxing, tennis, and personal training.

Although other companies competed with EA Sports throughout the 1990s and into the twenty-first century, Take Two Interactive's daughter company, 2K Sports, and first-party companies such as

Sony and Nintendo presently exist as its primary competition. 2K Sports and Sony have created games that rival EA Sports, and Nintendo has used its Wii motion controller to promote its popular *Wii Sports*.

GAME TYPES

The sports game genre can be divided into various subcategories that lie on a simulation continuum. Games that attempt to realistically simulate outcomes exist at one end, and games that have little interest in realistic outcomes are at the other (Conway 2007).

The first category of sports games features those that attempt to simulate the outcomes of real-world sport to the greatest degree. Conway (2007) calls these games “management simulations.” Typically, players call these types of sports games “text sims” (short for “simulations”) and predominantly play them on a personal computer. They are often geared toward players who want to manage or coach a team rather than control its players. As a result, the text sim emphasizes strategy and planning more than quick reflexes. The *text sim* label has been applied to this type of game because much, if not all, of a given game’s action occurs via text. The player does not see his or her team move around a virtual field or stadium. Instead, the player reads the outcome of a specific play in game reports or learns what has occurred through statistical information. This statistical information serves as the key focus of the text sim.

Text sims strive to achieve realistic statistical outcomes. As such, the computer’s power is dedicated to complex calculations to generate plausible results.

Recent titles in this subcategory of sports games have begun to integrate simple graphical representations of in-game action, but many text sims still leave these graphics out of gameplay. Because they do not emphasize graphics that require large development teams, these games are often developed independently by individuals or small studios. Examples of text sims include the *Football Manager* series, the *Out of the Park Baseball* series, and the *Front Office Football* series.

At the opposite end of the spectrum are a subcategory of sports games that make no attempt to achieve realistic statistical outcomes. Conway (2007) labels these games “extreme simulations.” Extreme simulations are predominantly played on home consoles. They are intended for the player who has little or no interest in whether a virtual athlete performs at the same level in the game as in real life. In contrast to text sims, these games are not concerned about accurately simulating games, seasons, or careers. Instead, extreme simulations emphasize a fast pace and exaggerate the most exciting elements of the sports they represent. As players control their teams, the athletes in these games can perform actions they could never perform in real-world sports. One of the first widely popular extreme simulations was the arcade hit *NBA Jam* (1993) from Midway Games. The most prominent publisher in this category is EA Sports Big. Examples of games in this category include the *NBA Street* basketball series, *The Bigs* baseball series, and the *SSX* snowboarding series.

In between these two extremes of dedicated statistical realism and little, if any, focus on believable outcomes are those

sports games that attempt to simulate real-world sports but allow the player to directly influence results. Conway (2007) calls these types of games “action simulations.” Action simulations are most often played on home consoles but are also played on personal computers. They are intended for players who want to take control of their favorite teams and athletes to see if they can do better than their squad’s real-world performance. Like management simulations, these games aim for statistical plausibility. Like extreme simulations, these games allow for players to control the athletes on the screen. However, games in this category differ by providing a middle ground between realistic statistical outcomes and the actions players can control on-screen. Unlike management simulations, action simulations do not demand realistic statistical outcomes. Unlike extreme simulations, action simulations do not allow players to move in physically unrealistic ways. As a result, these types of sports games provide a middle ground between the other two categories through detailed graphical realism that replicates the nuances of stadiums as well as athletes’ appearance, equipment choices, and athletic movement. In action simulation games, players see something similar to what they would see while watching a sporting event on television. Examples of action simulations include the *Madden Football* series, the *FIFA Football* series, and the *NBA 2K* series.

The most recent trend to find its way into sports games, irrespective of sub-genre, concerns card-collecting modes. The mode first appeared in EA’s *Champions League* football game in 2006–7, but it has since spread to games across the

genre. Players open digital packs to acquire virtual player cards reminiscent of their cardboard predecessors. These packs can be acquired by preordering titles, playing the game, or by direct purchase. Most cards feature an athlete, a coach, a stadium, or a sport-specific power-up. Players subsequently collect cards and create their own teams that they can use to compete off-line or online. These modes have been incredibly profitable. In the 2017 fiscal year, EA reported that its version of the mode, *Ultimate Team*, produced almost a fifth of the entire company’s total revenue (Ballard 2017).

LICENSES

One of the most important issues in the history of the sports game has been that of licenses. Professional sports leagues and organizations recognized that additional revenue could be gained from sports video games and subsequently began selling licenses to game developers. Game developers realized that sports game players would be more likely to purchase games featuring real teams and athletes. These licenses allowed developers to use real team names and logos and the names and likenesses of real players.

The first licensed sports game appeared in 1983 with the release of EA’s basketball title, *Dr. J and Larry Bird Go One on One*. Over the course of the next twenty years, licensing became quite commonplace. However, in 2004, the licensing landscape changed considerably. Throughout the late summer and early fall of 2004, rival game publishers 2K and EA Sports fought a battle for consumer loyalty over their football titles.

2K's *ESPN NFL 2K5* (2004) competed against EA Sports' *Madden Football 2005* (2004). 2K had sold its game for \$19.99, well below that of EA's offering. *ESPN NFL 2K5* sold well enough that it began to bite into EA's considerable *Madden* customer base. On December 13, 2004, EA announced that it had signed an exclusive five-year deal with the National Football League, making EA the only company that would be allowed to produce football games featuring NFL teams, logos, stadiums, and players. On February 12, 2008, EA extended the agreement through the 2012 season. Although EA had negotiated exclusive deals with other less popular professional sports organizations before, the magnitude of this agreement was a watershed in sports game history.

In 2005, rival publisher, Take Two, struck a similar deal with Major League Baseball (MLB) that provided Take Two with exclusive rights to MLB and its associated properties. This agreement did allow console makers to develop MLB games, but it prevented other developers and publishers (like EA) from making games using professional players and teams.

To take advantage of these exclusive deals, sports game developers have increasingly begun to release licensed titles in each of the three subgenres previously outlined. For example, after EA Sports' agreement with the NFL, the company not only continued publishing the action simulation *Madden Football* but also developed the extreme simulation *NFL Street* and the management simulation *NFL Head Coach*. In a similar way, 2K expanded its action simulation *MLB 2K* baseball series into the extreme simulation *The Bigs*, and the

management simulation *MLB Front Office Manager*. With the advent of lucrative card-collecting modes in action simulation games, the extreme and management simulation subgenres have been dropped by mainstream publishers.

These exclusive licensing deals were not welcomed by all. In 2009, lawsuits were filed against EA and the National Collegiate Athletics Association (NCAA) by former Arizona State quarterback Sam Keller and UCLA basketball player Ed O'Bannon. Keller and O'Bannon charged the company with failing to compensate collegiate athletes for using their likenesses in the company's games (Associated Press 2009; Nocera 2016). EA eventually settled the cases by compensating twenty-nine thousand former college athletes from a pool of \$60 million. College sports games have disappeared, with many attributing the disappearance to these cases. Some gamers have also had problems with these exclusive licensing deals. Less than six months after EA extended its agreement with the NFL, two gamers filed a class action lawsuit against the company, charging it with anticompetitive activity (Sinclair 2008).

Square Enix

Square Enix is a Japanese video game developer, publisher, and distributor with

several large titles in its arsenal of games, including the *Tomb Raider*, *Final Fantasy*, and *Dragon Quest* series of games. The company came into being through the merger of Enix and Square, two Japanese video game companies. Enix was a video game publishing company started by Yasuhiro Fukushima in 1975, and Square was a game design company started in 1983 by Masafumi Miyamoto; the two companies initially worked together to design and publish the *Dragon Quest* series. Both companies were among the largest video game developers in the 1990s, and in 2000, they began to discuss a merger, though it was postponed for several years due to Square's first feature film, *Final Fantasy: The Spirits Within* (2001), which flopped, losing close to \$82 million.

After the turnover of several higher-ups at Square, including Tomoyuki Takechi as chairman and Hironobu Sakaguchi as executive vice president, Yoichi Wada stepped in as CEO in December 2000 and ultimately became responsible for paving the way for the merger. Under Wada's guidance, Square recovered financially between the failure of *Final Fantasy: The Spirits Within* and the merger with the release of *Kingdom Hearts* in 2002. In April 2003, Square and Enix finally became one company under the name of Square Enix. Wada became the new president of the company, and Enix's president, Keiji Honda, became the vice president. Square was ultimately dissolved in the merger, and Enix became the remaining company.

After the merger, Square Enix began to acquire a number of companies, both gaming-related and non-gaming-related, including Taito, creator of *Space Invaders* (1978), and Eidos Interactive, publisher of the *Tomb Raider* series. In 2008, the corporation became known as Square

Enix Holdings, with subsidiary companies responsible for developing and publishing still under the name Square Enix.

Square Enix has continued to create content for different gaming platforms and media outlets, a strategy that Square Enix's European division's president has called a "polymorphic" move. The company has focused on producing video games for all of the major gaming platforms available, and it also does game development for handheld gaming devices. Its most popular works include the *Final Fantasy*, *Dragon Quest*, *Tomb Raider*, and *Call of Duty* series.

StarCraft

StarCraft is a real-time strategy (RTS) computer game designed by Chris Metzen and James Phinney, developed by Blizzard Entertainment, and released March 31, 1998. Its expansion, *Brood War*, came out in November of that same year. The *StarCraft* universe further expanded in novels and mangas, and a sequel, *StarCraft II*, came out in three parts: *Wings of Liberty* (2010), *Heart of the Swarm* (2013), and *Legacy of the Void* (2015). The *Remastered* version of the game was released in 2018. It used the same game engine but supported wider resolutions, more detailed 2-D graphics and sound, new cutscenes, and a matchmaking and ladder system similar to modern strategy games. The original game, along with its expansion,

became free-to-play (F2P) the same day the *Remastered* version was released.

While it was a new step in the RTS genre for Blizzard after the success of *Warcraft II: Tides of Darkness* (1995), *StarCraft* has a science fiction setting: three species are fighting each other in a sector of the galaxy. The Terrans are humans, redneck criminals exiled from Earth a long time ago. The Zergs are giant insect-like creatures of various forms morphed from larvae and controlled by a central brain. The Protoss are thin aliens that gain their power from psychic capabilities and robotic technologies. Each species is not only fighting the others; there are also internal struggles within each species for different interests in the galaxy.

The game follows most of the genre's conventions and is considered a leading example of a balanced asymmetrical RTS. Players must establish a base and collect resources (minerals and vespene gas) to build military units and lead their armies into combat. The game uses a mouse and keyboard as controllers, and players click on units and buildings to issue orders, which are carried out automatically. Units and buildings have different characteristics (hit points, attack score, armor, etc.) and special abilities that influence the results of combat. Each power-up in the game is ordered in a *tech tree*: in addition to an amount of resources needed, the construction of certain buildings is a prerequisite for new units, buildings, technologies, and upgrades. Collecting resources implies that the player constructs and defends new bases all over the map. The Zerg must erect most of their buildings on the *creep* (a living superorganism) that their Hatcheries secrete, while the Protoss must construct Pylons and build around them. Standard

A person playing *StarCraft II* at a gaming convention. (Ppl/Dreamstime.com)

games are over when a player (or a team of allied players) destroys all of his or her opponents' buildings.

The narrative consists of six single-player campaigns; three in the original game and three more with the expansion. Each campaign is an episode of the whole storyline and allows the player to gain control of a specific faction (Terran, Zerg, or Protoss). The player has to fulfill the objectives of a scenario to move on to the next objectives, which could be as diverse as “survive for 30 minutes,” “bring a unit to a specific location,” or simply “destroy the enemy camp.”

The first drafts of the game were very similar to Blizzard Entertainment's precedent work in the RTS genre, *Warcraft II: Tides of Darkness* (1995). In 1998, *StarCraft* still used two-dimensional graphics, even though other RTSs had already begun using three-dimensional graphics in 1997 (such as *Age of Empires*

and *Total Annihilation*), and it borrowed many gameplay elements from its predecessors. Nonetheless, *StarCraft* raised the standards in several ways.

First, as in the already established *Command & Conquer* series, the story is delivered through deep character development and impressive voice acting. At the time, most storylines in RTSs were given between scenarios—sometimes as text only—and could easily be skipped without losing the overall feeling of the game. However, at the core of its narrative and campaign gameplay, *StarCraft* features “heroes” who are characters as well as in-game units; these heroes talk to the player and to each other between the scenarios and during the game, resulting in gaming sequences that are more involved in the campaign narrative.

Second, *StarCraft* is considered one of the most balanced multiplayer RTS games, meaning that the unique characteristics

of each faction do not give them advantages over the other factions. This balance is asymmetrical: each of the three races has a different set of units, buildings, technologies, and special abilities, as opposed to most RTS games of the time that had identical or very similar factions. Twenty years after the original release, the three races are still balanced, and the number of patches needed to maintain this balance is surprisingly low, especially compared to today's standard in competitive games—including the *StarCraft II* installments.

Third, in terms of gameplay, the importance of speed and micromanagement is one of *StarCraft*'s defining characteristics. Players have to balance their actions between macromanagement and micromanagement: an economic or technological advantage will usually ensure victory in the long term, but unit control is an important factor in combat and is essential for most of the special abilities. Speed is crucial to competitive play; professional gamers have to play at around three hundred actions per minutes or more. Strategies relying on execution skills are something derogatorily dubbed “cheese”; the infamous “Zerg Rush”—a fast attack with Zerglings, the cheapest unit of the Zerg faction—being one of the most common examples of cheese.

Moreover, the *StarCraft* “campaign editor” had functionalities that made it possible for players to create scenarios where the rules of the game are changed. The Battle.net server, Blizzard Entertainment's gaming network, hosted custom games with special rules that changed the gaming experience. For example, the map “Aeon of Strife” contained the main features of the

multiplayer online battle arena (MOBA) genre, such as a lane-based map and heroes gaining upgrades and skills; many maps popularized the tower defense genre. Other players preferred the “ladder” side of the multiplayer games, a mode using only a set of approved maps, where the game keeps score of the players' results. Although Blizzard did not support a ladder system for *StarCraft* for more than a decade before the release of the *Remastered* version, elite players could still challenge each other within a similar system through third-party servers, such as ICCup.com.

What makes *StarCraft* unique, though, is the fact that it gained the status of an esport and saw the emergence of a professional gaming scene in South Korea at the turn of the millennium. *StarCraft* was nationally regulated via the Korea e-Sports Association (KeSPA) founded by the South Korean government. Television channels broadcast hosted leagues, such as the Ongamenet Starleague (OSL) and the MBCGame Starleague (MSL). South Korean companies sponsored professional teams—for example, Samsung KHAN and SK Telecom T1—and *StarCraft* pro gamers were the first cyber athletes to be celebrities. Although other games are played in competitions all over the world, *StarCraft* is one of the first and most long-lasting of them and has been a part of the World Cyber Games since its beginning in 2000.

If the RTS is sometimes thought to be a genre in stagnation, *StarCraft* was released at the pinnacle of its golden age. Even though other RTSs have a certain audience in the professional gaming scene, *StarCraft* already has a place in video game history for its exemplary use of the conventions of the genre and for

having held gamers' and spectators' interest for more than two decades.

Stealth Games

Stealth is a gameplay style that involves sneaking, subterfuge, and secrecy as opposed to direct engagement. The main player activity usually involves navigating an avatar around an environment full of dangerous opponents, all of whom are initially unaware of the player's presence. The player attempts to maintain this secrecy for as long as possible while being engaged in other activities. What these activities are depends greatly on the game, but common ones include theft, sabotage, escape, and assassination. The ease with which these goals are achieved can often be strategically adjusted by eliminating opponents. The most typical form of elimination involves sneaking up behind opponents to subdue them, often referred to as a "stealth kill" or "stealth takedown," depending on whether the move is lethal or nonlethal.

If the player makes a mistake and is discovered, gameplay usually switches to some sort of action-based schema involving gunplay or melee combat. Depending

on the game, the player's avatar may be weak in combat or strong, making the penalty for mistakes very different. In some games, the only course of action in the event of being discovered is flight. In others, it may be possible to take out all opponents in a head-on confrontation. The avatar's combat prowess often determines to what extent stealth is a necessity or a choice, making the centrality of stealth to a game's generic identity somewhat flexible.

A game can emphasize stealth as a major style of play, a minor style of play, or on equal footing with direct confrontation. Some games emphasize stealth as a major style of play, even with a combat-ready avatar, by punishing the player for being seen by means other than death (such as a bad "stealth rating" or loss of resources). The natural rhythms of stealth gameplay are essentially the sustained tensions of a game of hide-and-seek, with long periods of silence and secrecy punctuated by quick bouts of frantic action.

The history of stealth in games may be described differently depending on whether one is talking about stealth as a gameplay style or stealth as a genre. Stealth as a gameplay style appeared to a lesser or greater degree in many games before it became recognized as a genre, and it still crops up in games even when the genre is not exclusively stealth. The earliest example of stealth gameplay is arguably *Castle Wolfenstein* (1981), a top-down shooting game in which it was advantageous to shoot Nazis from behind. *Metal Gear* (1987) is another, more complicated example of early stealth gameplay, with a fully developed military espionage setting that gives context and coherence to its gameplay. Because of

Metal Gear's great emphasis on stealth (sneaking was not just the best strategy but the only strategy), it has been retroactively labeled a stealth game by some, even though the term was never applied to *Metal Gear* by its own makers. The third *Metal Gear* game, *Metal Gear Solid* (1998), coined the term "tactical espionage action" in reference to the fact that the gameplay alternated between sneaking and spectacular action set pieces. This combination kept *Metal Gear*'s relationship to the emerging stealth genre ambiguous, even though it pioneered much of the genre's foundational concepts.

Other games emerging around the same time as *Metal Gear*, such as *Thief: The Dark Project* (1998), *Tenchu: Stealth Assassins* (1998), *Commandos: Behind Enemy Lines* (1998), and *Hitman: Code-name 47* (2000), were more visibly laying the groundwork for stealth as a genre, given that they relied almost completely on sneaking and offered far more brutal consequences for failure. Such games were successful in their employment of stealth gameplay but were also somewhat experimental. It was not until around the time the Tom Clancy–licensed espionage game *Splinter Cell* (2002) was released that the phrase *stealth game* began to emerge as a descriptive phrase for what had already become an obvious trend in game design.

After this initial stealth boom in the late 1990s and early 2000s, there have been few new pure stealth franchises. Rather, stealth gameplay began to crop up in other genres to a lesser or greater degree. Action-adventure series such as *Tomb Raider* and *Uncharted*, cartoon platformers such as *Sly Cooper*, and movie and comic book character tie-in series such as *The Chronicles of Riddick*

and the *Batman: Arkham* games incorporated stealth as major gameplay elements. The survival horror genre, a natural match for stealth because of its reliance on weak protagonists versus strong enemies, has increasingly embraced the form in the *Siren*, *Amnesia*, and *Last of Us* series and in games such as *Alien Isolation* (2014). Long-standing role-playing franchises such as *Fallout* and *The Elder Scrolls* and games such as *Vampire: The Masquerade: Bloodlines* (2004) have also increasingly embraced stealth as a major playstyle, and while this style is partially rooted in classic pen-and-paper role-playing games (RPGs), the particular way these franchises have applied stealth to immersive three-dimensional worlds owes more to video games like *Thief* than it does to tabletop games.

With the explosion of the indie scene in the late 2000s, there has been a plethora of genre-bending stealth titles, including *Mark of the Ninja* (2012; 2-D platformer stealth), *Invisible, Inc.* (2015; turn-based strategy stealth), *Volume* (2015; puzzle stealth), and *Republique* (2016; point-and-click adventure stealth), suggesting the form's healthy survival as distribution and markets evolve. The genre that seems to have the strongest relationship with stealth gameplay is the immersive sim, the origins of which are themselves tied up in the initial stealth boom. Direct revivals such as *Deus Ex: Human Revolution* (2011), *Thief* (2014), and *Hitman* (2016) as well as spiritual successors such as the *Dishonored* series have been the torchbearers for the more systemic, immersive flavor of stealth that established the form, as have long-running blockbuster stealth franchises such as *Metal Gear* and *Splinter Cell*.

These types of games do seem to be bleeding into another genre, the open-world game, which is probably the genre with the widest footprint that has most consistently embraced stealth as a major gameplay style. Monster franchises such as *Grand Theft Auto* pioneered stealth in an open-world context so that today we see it in most games of this type, from *Horizon: Zero Dawn* (2017) to *The Legend of Zelda: Breath of the Wild* (2017). Indeed, the largest open-world franchise in existence, *Assassin's Creed*, has stealth as its foundational gameplay type, and even the longest-running stealth game franchise, *Metal Gear*, expanded to an open-world model in its final installment, suggesting that the pairing of stealth and open-world gameplay will remain a norm in games for some time.

It is unclear whether stealth will mainly become a component of open-world game design or whether it will continue to experience revivals in games of smaller scope. In any case, from its origins, it seems to have left enough of an impression on general trends in game design to remain a recognizable gameplay style for future developers to employ for whatever purposes they choose.

Steam (Portal)

Steam is a multiplatform digital distribution portal that provides users with a variety of features, including game downloads, automatic updating, match-making servers, and cloud-saving services. Steam allows users on PC, Mac, and Linux computer systems to download and play games with friends across all these computer systems, and it can be used on mobile platforms and streamed to televisions as well. Developed by Valve Corporation, Steam also provides a community forum where players can interact with other Steam users. The official release of Steam occurred on September 12, 2003, as Valve attempted to create a portal to help distribute and promote updates for its online games. Originally featuring only Valve games, Steam began to take off in 2004 when Valve required the use of Steam to play its critically acclaimed *Half-Life 2* (2004). In 2005, non-Valve games became available on Steam, and in 2006, over one hundred different games could be downloaded there. With a variety of unique marketing techniques, such as a Top Sellers category, sales listed by percentages, and an integrated search function, Steam became a front-runner in the digital sales of video games.

In 2008, Steam also introduced the software development tool Steamworks to invite game developers to optimize their games for the Steam interface, allowing anyone to publish their games on Steam. Steam has been attempting to compete in the competitive streaming and hardware markets with limited success. Steam TV streams esports and other game events in an effort to compete with Twitch as a streaming platform.

Steam also released Steam Machines, which are computer gaming systems optimized to work with the Steam library of games. Partners of the Steam Machines include popular computer gaming companies such as Alienware and Syber. Steam Greenlight, which transitioned into Steam Direct, is a publisher program that allows game developers a chance to distribute their games independently through the Steam platform. All in all, Steam is attempting to be a complete gaming platform for players, developers, and gaming industry professionals.

Steam's digital library now has thousands of games available for purchase and download including nostalgic favorites of longtime gamers and more recent popular online games. Their top games for players include *PlayerUnknown's Battlegrounds* (PUBG Corporation, 2017), *Dota 2* (Valve Corporation, 2013), and *Counter-Strike: Global Offensive* (Hidden Path Entertainment & Valve Corporation, 2012).

Strategy Games

A strategy game is one that emphasizes thoughtful and planned use of resources to achieve victory. The genre has a long history; it was a prominent part of the early history of video games, and it is still a significant part of today's video game

industry and culture. Because strategy games typically demand extended play sessions, they were better suited to the early mainframe and home computer platforms than the quarter-swallowing, short-play action games of the arcade. The genre is still strongly associated with personal computers. There are numerous varieties of strategy games, and many other genres, such as role-playing games (RPGs), platform games, and even action games incorporate strategy elements.

Within the domain of video games, the term *strategy* usually applies to things such as the management and development of in-game resources, such as the wood and gold of *Warcraft III* (2002); the judicious timing of combat or other kinds of conflict, such as taking an opponent's piece in *Battle Chess* (1988); and the exploration of game worlds to gain advantages, such as sending scout units to discover the world map in *Civilization II* (1996). All of these actions have costs and potential benefits. For example, exploration in the *Civilization* games requires the player to spend build points creating scout units and requires tasking those units to exploration when they could be doing something else. These costs are balanced by opportunities to find valuable resources to exploit, scout enemy military forces, and discover new locations to build cities. The player must therefore make strategic decisions about the amount, speed, and kind of exploration to engage in. Inevitably, different kinds of strategic decisions have an impact on each other: creating exploration units has an impact on economic planning and military options.

Video games that are called strategy games always emphasize deliberate planning of gameplay decisions. This often means these types of games usually place

little or no emphasis on the motor skills of a player, such as in the turn-based game *X-COM 2* (2016). Many strategy games, such as *Company of Heroes 2* (2013), are indeed fast paced, but whatever benefits a player's speed and reflexes grant, intelligent play is crucial to beating an opponent of a similar skill level. In addition, many games that are *not* called strategy games incorporate video game elements that are typically part of the strategy genre. For example, most games labeled "simulations"—such as *Cities: Skylines* (2015)—involve careful strategic management of resources. Even action and RPGs, such as *Fallout 4* (2015), allow for strategic investments and character development that are reminiscent of strategy gameplay.

The line between strategy and tactics in video games is a contested one. Typically, the word *strategy* applies to decisions that affect the global state of gameplay (such as which technologies to pursue in *Rise of Nations* [2003]) or games that focus on high-level decision making (such as Chris Crawford's *The Global Dilemma: Guns or Butter* [1990], which involves a player determining whether a country should invest primarily in military might or economic development). *Tactics* usually apply to decisions that affect only parts of the game (such as orders given to units in combat in *StarCraft* [1998]) or to games that focus on unit-level decision making (such as the action/role-playing/strategy hybrid *Valkyria Chronicles* [2008] or the building/combat game *Fortnite* [2017]). In other words, strategy games will typically focus on things such as geopolitics, management of economic systems, or the movement of entire armies, whereas tactical games may look at managing an

individual political campaign or controlling a limited number of units on an individual battlefield. In practice, however, the terms are often used interchangeably.

Strategy games have a very long history. Arguably, most of the classic board games existing before the video game era—such as the ancient Egyptian game Senet, chess, or Monopoly—are strategy games. However, most of today's strategy video games find their roots in some way, shape, or form in modern war gaming, which dates back to military training games developed in the 1800s. Although armies continued to train officers this way in the twentieth century, small groups of war-gaming enthusiasts played similar battle and war simulations for entertainment. These board games ranged from simple ones like *Risk* (1959), to complicated, detailed recreations of war, like Avalon Hill's *Blitzkrieg* (1965). This gaming culture gave birth to RPGs (via Chainmail [1971] and *Dungeons & Dragons* [1974]) and set the style and tone for early strategy games.

The mainframe computer culture of the 1960s and 1970s produced a number of text-based strategy games whose program code circulated freely and constantly morphed as programmers modified the games. *Civil War* (1968), for example, simulated high-level strategic approaches to Civil War battles. Peter Langston's *Empire* (1972) is a multiplayer conquest game, and *Hamurabi*, first developed by Doug Dyment as *The Sumer Game* (1968), is an extremely influential economic management game set in ancient Sumer. Other early games with strategic elements include Gregory Yob's maze puzzle game *Hunt the Wumpus* (1972) and the pioneer-themed travel game *The Oregon Trail* (1971).

Most of these games were ideal for the new home computer market of the 1970s and early 1980s, as the programs required few graphic capabilities and little processing power. Text-based strategy games were released as line-by-line programs in computer enthusiast magazines such as *Creative Computing*, but by the 1980s, some games were marketed as a manufactured product, usually featuring at least rudimentary graphics, and were sometimes almost as visually advanced as home computer action games. Examples include the space colonization management simulation *M.U.L.E.* (1983), the New World conquest game *The Seven Cities of Gold* (1984), and SSI's space empire-builder *Imperium Galactum* (1984). More action-oriented games had significant strategic elements, such as the cartoon combat game *Spy v. Spy* (1984) and the medieval knight simulator *Defender of the Crown* (1986).

Several important subgenres of strategy games became industry standards in the 1990s. The release of *Sid Meier's Civilization* (1991) helped to create the "4X" (eXplore, eXpand, eXploit, eXterminate) subgenre, a term coined by Alan Emrich in 1993 and widely used today by gamers and the game industry. These games are typically large-scale, highly complex games that require players to explore worlds to find resources necessary to grow their power and defeat their enemies. Games explicitly identified as 4X are typically turn-based strategy games. Whereas *Civilization* was hardly the first game to incorporate these gameplay elements—some aspects of the subgenre clearly date back at least as far as *Hamurabi*—its success encouraged the publication of a spate of similar games, such as *Masters of Orion* (1993), *Masters of Magic*

(1994), and *Colonization* (1994). These games are also often called *god games* because they give the player godlike powers over vast territories, cultures, and stretches of time.

A larger commercial subgenre (and one that is well defined and recognized in the gaming industry and community) is the real-time strategy (RTS) game that effectively started with *Dune II* (1992). These games, like many 4X games, typically emphasize the accumulation of resources and production of combat units. However, game action is real time, not turn based, and most RTS games require the construction of buildings in a base to progress and create units. Again, several games with similar gameplay elements, such as *The Ancient Art of War* (1984), preceded *Dune II*, but the latter game very quickly inspired a large group of similar titles, such as *Warcraft: Orcs & Humans* (1994), *Command and Conquer* (1995), *Age of Empires* (1997), and *StarCraft* (1998).

Around 2003, a mod of *Warcraft III*, called *Defense of the Ancients (DOTA)*, drawing on previous titles, effectively introduced an RTS variant genre known as the multiplayer online battle arena (MOBA). This genre reached global prominence with games such as *League of Legends* (2009) and *DOTA 2* (2013). These games feature combat similar to their RTS predecessors, but they have no base building or resource gathering and a predictable, fixed map. In fact, these games are often more tactical than strategic, but they do have a close connection with RTS games.

The explosion of mobile games following the introduction of the first smartphones led to a popularization of strategy games for a more casual market. Titles

such as *Clash of Clans* (2012) and *Mobile Strike* (2015) are simpler than a full-fledged turn-based game like *Civilization*; consequently, they appeal to a wider audience and have at times generated immense followings and substantial revenues: in 2015, *Clash of Clans* averaged around \$5.5 million revenue per day.

Strategy games fall into a number of categories (beyond the well-defined subgenres previously listed). One of the big division lines among strategy games is whether they are turn based, such as the fantasy war game *Heroes of Might and Magic* (1995), or real time, such as *Syndicate* (1993). The former waits for players to complete turns before the game proceeds, and the latter allows activity to continually occur, whether the players act or not.

Another distinguishing characteristic that divides strategy games is whether they are real-world simulations. Strategy classics such as the *Civilization* and *SimCity* series attempt to model actual history, economic development, and political systems, whereas digital versions of games such as Go and backgammon are clearly abstract. And many strategy video games simulate fantasy worlds, such as *Age of Wonders 3* (2014).

Strategy games also vary in terms of the number of players involved and to what degree artificial intelligence (AI) is involved. Many strategy games are single-player games in which the player struggles against the computer, such as the original *Civilization*. Other games, such as *Dominions 5: Warriors of the Faith* (2017), feature both single-player campaigns and multiplayer styles of play. Multiplayer games can allow for “hot-seat” play (multiple humans taking turns on the same computer, such as in *Gold of the Americas* [1989]); play over the

internet or local networks, such as *Total War: Warhammer II* (2017); or the computer taking the role of players via AI, such as in *Battle for Middle-Earth* (2004).

Streaming

The term *streaming* is used as a metaphor comparing the flow of digital content through a broadband connection to the continuous flow of water in a stream in nature. It is a method of presenting digital information continuously and receiving digital content, usually video or audio, continuously as it is being used, as opposed to downloading the entire amount of a program and storing it to be used later. *Livestreaming* refers to sending of the video or audio of an event as it occurs live, including the playing of video games.

Although the term developed in regard to digital media as an alternative to the downloading of a complete file before use, analog technology used streaming as well. Broadcast television programs were sent out in a continuous stream as well as radio; although such broadcasting is

generally not referred to as streaming, with the term mainly being reserved to digital media to distinguish it from downloaded or stored programs.

User requirements for streaming media include having enough bandwidth to receive the stream of data and the right software to interpret and display the data in real time. Streaming services include video services such as Netflix, Amazon Prime, Hulu, and others as well as audio services such as Spotify and Apple Music. Subscribers to these services pay a monthly fee for the use of the service, and that use is usually limited to a set number of devices that can use the service at any given time.

Streaming has changed the marketing of digital content, from the rental of videotape and optical disc storage to direct streaming over the internet, requiring users to have an internet provider. Unlike the use of storage media, the content can become unavailable if something happens to it at the site of origination or due to signal degradation along the way. Streaming also affects movie collecting; instead of owning a movie on a disc, you can only rent access to it for a limited amount of time. The streaming of copyrighted material without permission may also be considered infringement, even though no copy of the material is stored.

During the mid-2010s, the streaming of live video game play became popular on sites such as YouTube and Twitch. By 2014, there was more streaming traffic on Twitch than on HBO's online service. In 2015, YouTube started the subsite YouTube Gaming to compete with Twitch.

Street Fighter II

Street Fighter II refers to a subseries of six (excluding hacks and nonofficial modifications) fighting games developed by Capcom for the arcade. The first iteration, *Street Fighter II: The World Warrior* (1991), was built on several conventions established in the earlier *Street Fighter* (1987). In *Street Fighter II*, two characters engage in one-on-one combat using a variety of punches, kicks, and special attacks to deplete each other's health meters. When a character runs out of health, he or she is knocked out, and the opponent wins the round; the first to win two rounds wins the match. Rounds are also timed: if both characters are still standing when time runs out, the round goes to the player with the most health remaining.

The game is played with an eight-way joystick and six attack buttons, corresponding to three punches and three kicks of varying strength and speed. Each character also has a variety of “special moves,” which are performed by inputting a series of directions and then pressing an attack button.

Street Fighter II: The World Warrior is often credited with sparking the fighting game craze that swept the United States in the early to mid-1990s. At the peak of the craze, *Street Fighter II* cabinets could be found in many retail locations, including liquor stores, bowling alleys, and

convenience stores, in addition to traditional video arcades. In the game, there are eight characters players can choose from and four unavailable “boss” characters. In the single-player mode, the player chooses a character and then fights the seven other characters followed by the four boss characters. The single-player mode also includes bonus rounds, including the now iconic game in which the player must destroy a car. In the two-player version, each player picks a different character, and they play against each other. The winner stays in the game, and the loser must insert another coin to continue play.

Street Fighter II eventually went through five revisions. Although each featured numerous minor changes and balance adjustments, only the major changes will be noted here. *Street Fighter II: Champion Edition* was released in April 1992 and allowed players to choose from the four boss characters, bringing the available character count up to twelve. *Street Fighter II: Hyper Fighting* (December 1992) is widely believed to be a response to the growing number of hacked *Street Fighter II* cabinets. This revision drastically increased the speed of the game and introduced new special attacks for several characters. The fourth installment, *Super Street Fighter II: The New Challengers* (October 1993), added four new characters and returned gameplay to its original speed. This latter decision was widely unpopular. *Super Street Fighter II Turbo* (March 1994) increased the game speed again and added “super combos.” Characters now had a meter at the bottom of the screen that filled as they performed attacks. Once full, the character could unleash a powerful super combo attack. The final

arcade release, *Hyper Street Fighter II* (December 2003, Japan only), allowed players to choose characters from any *Street Fighter II* version to fight against a character from any other version. For example, Ken from *World Warrior* could fight Cammy from *Super*. This version eventually saw release in the United States as part of the *Street Fighter Anniversary Collection* on the Sony PlayStation 2 (2004) and Microsoft Xbox (2005).

Strong National Museum of Play

Opened to the public in 1982, the Strong National Museum of Play is a history museum in Rochester, New York, that owns and cares for the world’s most comprehensive collection of toys, dolls, board games, video games, jigsaw puzzles, books, documents, and other historical materials related to play. The museum uses these collections to explore play and the ways it encourages learning, creativity, and discovery and illuminates cultural history.

The museum’s 285,000-square-foot facility in Rochester explores the history and meaning of play in interactive exhibits that attract more than 550,000 guests a year. Among the long-term exhibits at the Strong are *eGameRevolution* (which

explores the history of video games), *Pinball Playfields* (on the history of pinball), *Game Time!* (on the development of board games in the United States), and a display on the Academy of Interactive Arts and Science's D.I.C.E. award winners. The museum also regularly produces online and temporary exhibits, such as *Atari by Design* (2013), *Playing with Power: Celebrating 30 Years of the Nintendo Entertainment System* (2015), *Raceway Arcade* (2017), and *The Oregon Trail, MECC, and the Rise of Computer Learning* (2017).

To create these exhibits, staff at the Strong draw on the museum's unmatched and rapidly growing collection of more than five hundred thousand artifacts related to play. This unprecedented assemblage offers a unique interpretive and educational window into how play reflects cultural history and the critical role of play in human physical, social, emotional, and intellectual development.

The Strong's collections are accessed by scholars from all over the world, who are often supported by museum-funded research fellowships. The museum also publishes the *American Journal of Play*, a peer-reviewed, interdisciplinary journal that discusses the history, science, and culture of play. The journal aims to increase awareness and understanding of the role of play in learning and human development and the ways in which play illuminates cultural history.

The Strong has been collecting, preserving, and interpreting the history of video games since 2006, largely under the auspices of the International Center for the History of Electronic Games. The museum's collection of more than sixty thousand video games and related artifacts ranges from early arcade games to

the most recent downloadable indie games. The Strong is also home to the National Toy Hall of Fame and the World Video Game Hall of Fame, which annually inducts games based on criteria of icon status, influence, geographic reach, and longevity.

To facilitate its long-term growth, the Strong is undertaking a major 100,000-square-foot expansion, expected to be completed in 2021, which will feature major exhibits on the importance of video games.

Through all these activities, the Strong seeks to ensure that present and future generations understand the critical role of play in human physical, social, and intellectual development and the ways in which play reflects cultural history.

Subcreation

The term *subcreation* refers to the building of imaginary diegetic worlds within and across a variety of media. Originally coined by J. R. R. Tolkien, the term is used to distinguish human creation from God's *ex nihilo* creation as well as to indicate its reliance on the latter through the use of the *sub* designation (the term literally means "creating under"). Subcreation also refers both to the process and product of world-building while avoiding philosophically slippery terminology such as *real* and *imaginary*, which

tend to be seen as mutually exclusive domains. Unlike other approaches that are medium or narrative specific, the study of subcreation is concerned with the world itself, in which multiple narratives can occur and be viewed through a variety of media windows (such as film, television, comic books, novels, or video games). This approach is particularly well suited to video games, where diegetic worlds, unlike those of other media (e.g., film, television, print), contain an interactive element that often allows for navigation and exploration of the world under the player's control. Some video games are also part of larger transmedia worlds and thus must be considered with the rest of the world in mind, whereas others are self-contained and exist on their own within a single game or game series.

The study of subcreated worlds looks at each world as a whole and is concerned with the world's inner consistency as well as its global structures and the way in which they relate to the smaller-scale local structures within the world. Global structures include those of space (maps, layouts, connections between places); time (chronologies, histories, the timing of events); the genealogies, languages, and cultures of the world's inhabitants; and narratives that incorporate all of these. The worlds of video games, which range from simple single screens of flat graphics to elaborate three-dimensional online worlds populated by millions of characters, can also contain various ontologies and rules by which they operate, which players must learn when they vicariously inhabit these worlds through the use of avatars. Examining video games through a subcreative approach produces a more holistic view of their

diegetic worlds and one that is not limited by medium or narrative; rather, it looks at a world as a whole and something worthy of analysis in itself. As the diegetic worlds of video games grow larger and more detailed and complex, such an approach grows in relevance and provides a way to discuss the design of the world in such a way as to make it distinct from the design of the game as well as to discuss it in comparison to other subcreated worlds or to the appearances of the same world in other media.

Suicide Battery

Suicide battery is the term used by collectors to describe a small battery found in certain arcade games. This battery sends a current to the random-access memory (RAM) that holds a decryption table. The decryption key is used to decode the program code in the game's read-only memory (ROM), so when the battery dies, the RAM is erased. Without the decryption key, the game can no longer run. In

certain Capcom games, the suicide battery powers a custom chip that handles game graphics, which will not display correctly when the battery runs out.

Presumably installed to fight piracy, these batteries also limit the life of an arcade machine, leading many collectors to believe that the batteries were installed to require operators to buy more units as the old ones expired. Several companies used suicide batteries in their arcade games, including SEGA, which began using them around 1986; Capcom, whose system used them from 1989 onward; and Gaelco, an arcade game manufacturer in Spain. According to the Dead Battery Society's webpage, SEGA games using a suicide battery include *Action Fighter* (1986), *Alex Kidd and the Lost Stars* (1986), *Alien Syndrome* (1986), *Out Run* (1986), *Altered Beast* (1988), *Gain Ground* (1988), *Crack Down* (1989), *Golden Axe* (1989), *Laser Ghost* (1989), *Line of Fire* (1989), *Super Monaco GP* (1989), *Turbo Out Run* (1989), *Aurail* (1990), *Bloxxed* (1990), *Clutch Hitter* (1991), and *Desert Breaker* (1992). Capcom games using suicide batteries include *Adventure Quiz Capcom World* (1989), *Capcom Baseball* (1989), *Dokaben* (1989), *Super Buster Bros.* (1990), *Captain Commando* (1991), *The King of Dragons* (1991), *Three Wonders* (1991), *Adventure Quiz Capcom World 2* (1992), *Cadillacs and Dinosaurs* (1992), *Knights of the Round* (1992), *Warriors of Fate* (1992), *The Punisher* (1993), and *Saturday Night Slam Masters* (1993). Gaelco games using suicide batteries include *TH Strikes Back* (1992; also known as *Thunder Hoop II*), *Glass* (1993), *Alligator Hunt* (1994), *Touch and Go* (1995), *World Rally 2* (1995), and *Maniac Square* (1996).

To preserve the lives of their machines, some collectors have published

instructions on the internet that describe how suicide batteries can be removed and replaced without losing the current to the RAM holding the decryption key and also how to reprogram the EPROM (erasable programmable read-only memory), eliminating the need for a suicide battery altogether. In some cases, the encryption on the code ROMs has been broken, allowing the ROMs to be reprogrammed even if the battery has died and the decryption table is erased.

Super Mario Bros. See Mario Series

Super Nintendo Entertainment System (SNES)/Super Famicom

Nintendo released the Super Famicom in 1990 in Japan and the Super Nintendo Entertainment System (SNES) in 1991 in North America and 1992 in Europe. The naming choice was intended to leverage the widespread success of its predecessor, the Famicom/Nintendo Entertainment System (NES), which had dominated the home video game markets of Japan and North America after its release. Nintendo's plan was to sit back

and profit from Famicom/NES sales for years, but the looming threat of an upcoming competitor, the NEC PC-Engine console in Japan (eventually released in North America as the TurboGrafx-16), stirred the sleeping giant into announcing a follow-up 16-bit console in 1987—the Super Famicom—with promises of state-of-the-art technical capabilities. Its release allowed Nintendo to successfully counter the PC-Engine in Japan and to mitigate the success of the SEGA Genesis in North America (known as the SEGA Mega Drive in all other markets) during a heated console war from 1991 to 1995. Nintendo then lost the market lead to new rival Sony, which released the PlayStation, and its next console, the Nintendo 64, did not recapture the kind of market share Nintendo had been known for since the NES.

The SFC/SNES's development was an eleventh hour reaction to a technologically superior competitor, and as such, it faced a conundrum: it needed to match or exceed its competitor's technical capabilities to convince game developers and consumers that it would be the dominant next-generation system; yet, it also needed to be affordable like its 8-bit predecessor had been and to build upon its success. For more than a year, through press conferences and news reports, a backward compatibility feature (that would allow consumers to retain their Famicom game libraries) was said to be coming, but the costs of supporting Famicom games with the new hardware proved too costly in the end.

The displacement of the NES by the Super Nintendo Entertainment System (SNES) in the United States (meaning the need to invest into a new machine to replace the old) at a time when the NES

still enjoyed considerable success created a significant amount of negative consumer response that profited SEGA's quicker entry in the 16-bit generation, the SEGA Genesis. Even without backward compatibility, the rushed development and need to bridge with the past, combined with the need to cut costs and deliver a new console quickly, left a mark on the system's components and architecture. The Super NES, as evidenced by its name, is best understood as an extension or upgraded version of the same underlying principles that were responsible for the NES. To push games further in an era of rapid technological development, the overarching philosophy of the console was to use low-cost base components dedicated to specific functions and arranged in a modular architecture with expandability in mind for future proofing instead of gambling on a costly single and powerful central processing unit that should offer lasting performance for many years ahead.

The SNES sports a picture processing subsystem like the NES, but this time it had two dedicated units (PPUs): the PPU1 handling the regular sprite and background graphics and the PPU2 being responsible for special effects. A separate audio processing unit (APU) processes and outputs sound and music with eight channels of (severely limited) sound samples. The APU is especially notable for using Sony's SPC700 sound chip, marking the beginning of a relationship between the firms that would ultimately spawn the PlayStation. Finally, the SNES could integrate a peripheral through its expansion port and also stream data (and eventually offload processing tasks) directly from the cartridges, which would feature

custom enhancement chips to improve the baseline capabilities of the console.

Expansion chips were extensively used in many games, starting right from the system's birth with *Pilotwings* in 1990, but the expansion port was practically unused. Japan saw the release of the Satellaview in 1995, a satellite modem accessory that received broadcasts of varying nature following a schedule: games, digital magazines, news and advertisement, and so on. The most promising use of the expansion port was to be the SNES CD-ROM accessory, announced with great fanfare as a partnership with Sony to match the technological edge of Nintendo's competitors, but the CD-ROM was never marketed, as Nintendo stalled and announced another CD-ROM attachment with Philips, which failed to come through as well. A prototype unit of the Sony SNES-CD peripheral was recovered in 2016, stirring widespread interest in the case and the development of homebrew games to use the machine's specifications as hacks and thought experiments.

The technical components of the SNES were arranged around the needs and practices of game developers of the time, who had developed a number of techniques for programming NES games, such as implementing different scrolling backgrounds or displaying environments in pseudo-3-D perspective. The 16-bit successor automated some of these operations into a number of preset background graphical modes hardwired into the system. These eight graphical modes, set from 0 to 7 in the machine, allow different arrangements for up to four layers of scrolling backgrounds, with 4, 16, or 256 colors and differing properties for rendering graphics, such

as a pseudo-high-resolution setting, transparency, and color mixing.

Visually, the SNES was a huge improvement over the NES, and the complex interweaving of specific settings was reduced into simple (and high) numbers in the press releases and promotion for the console: 32,768 colors, 128 moving objects (sprites), and myriad special effects, such as parallax scrolling, mosaic tiling, zoom, rotation, and 3-D perspective. Nintendo claimed technical superiority with these numbers and promoted its unique "Mode 7" graphics that would create 3-D environments. In reality, Mode 7 performed matrix transformations (rotation, translation, scaling, and shearing) on 2-D planes, creating only *illusions* of depth and perspective, albeit convincing ones.

The system's architecture and approach of skirting around the promises of 3-D gaming illustrate Nintendo's mixed stance on technological innovation overall, particularly in the SNES era. Over the years, the SNES embraced the new horizons of the future of gaming, but from the current vantage point of established practices. Games that looked three-dimensional were still created and operated in layers of 2-D graphics. Full-motion video (FMV), powered by CD-ROM attachments, was gaining momentum on the PC, SEGA Mega Drive/Genesis, and NEC PC-Engine/TurboGrafx-16 front, but the announced SNES CD-ROM peripherals never materialized. The shift to full-fledged three-dimensional games, rendered in real-time through computer-generated polygons and simulation, was eschewed (save for a handful of cases—*Star Fox* [1993], *Vortex* [1994], *Stunt Race FX* [1994], *Dirt Racer* [1995], *Dirt Trax FX* [1995], and

Winter Gold [1996]—thanks to expansion chips); instead, computer-generated three-dimensional models were pre-rendered in high-quality animated frames, which were then integrated in classic 2-D genres in games such as *Donkey Kong Country* (1994) and *Killer Instinct* (1994). Games in fully simulated 3-D that were developed by Nintendo's expert partner Argonaut Software (who had been working with Nintendo since the development of the SNES, helping with *Pilotwings* and developing the Super FX chip integrated in *Star Fox* and many other high-profile games, such as *FX Fighter* and *Star Fox 2*) were not released.

The resistance to experimentation and the focus on lucrative and proven genres, steered in part by the system's architecture, was also the result of the business model and practices that Nintendo had imposed with the NES: an emphasis on high-quality games in fewer numbers, with appropriate care and consideration, as enforced through restrictive publishing agreements and a robust internal certification process before green-lighting games from third-party firms. In North America, Nintendo's tight control over the market, a classic "walled garden" approach to partnering with other firms, contrasted with SEGA's (and eventually even more with Sony's) more liberal licensing policy.

The competition forced Nintendo to soften its restrictive policies to accommodate its partners, particularly after the *Mortal Kombat* (1992) fiasco. Although the Genesis port of the highly violent arcade title kept all the blood and gore that contributed to its appeal (safely locked away behind a "secret code" that quickly became widespread knowledge as it circulated through video game

magazines), Nintendo forced Acclaim to tone down the SNES version, having characters lose gray "sweat" instead of blood during combat and similarly limiting the "fatality moves" to less gory variants. This version of the game was largely derided and tarnished Nintendo's image as a "kids' games" company, which played right into SEGA's marketing strategy of targeting older teens. Although the Genesis did not outsell or surpass the SNES (except in Europe and Latin America), Nintendo's public image was as damaged as its reputation among game developers, who considered its policies overbearing. When Sony moved in with its PlayStation in 1995, many gamers and game makers felt they were ready for more. Nintendo went from a totalitarian grip on the home video game console market with the NES to a modest lead with the SNES. This slow erosion would later continue with the Nintendo 64 and Nintendo GameCube systems.

The Super NES honored the NES's legacy of housing a wide variety of high-quality games and franchises. Worthy of mention are Nintendo's first- and second-party games *Super Mario World* (1990), *F-Zero* (1990), *The Legend of Zelda: A Link to the Past* (1991), *Super Mario Kart* (1992), *Star Fox* (1993), *Super Metroid* (1994), *Donkey Kong Country* (1994), and *Super Mario World 2: Yoshi's Island* (1995). While fighting games and arcade ports were the Genesis's forte, the SNES had its share with *Street Fighter II* (1992), *Fatal Fury* (1992), *Killer Instinct* (1994), and the previously mentioned *Mortal Kombat*.

One of the console's strong suits was role-playing games (RPGs), the bulk of which were developed by Square or published by Enix, rival companies that later

merged. Notable games included Square's *Final Fantasy 2* (1991), *Secret of Mana* (1993), *Final Fantasy 3* (1994), *Chrono Trigger* (1995), and *Super Mario RPG* (1996); Enix's conceptual action-RPG series *ActRaiser* (1990), *Soul Blazer* (1992), *Illusion of Gaia* (1993), and *Terranigma* (1995; released in Japan and Europe only) as well as other stand-alone titles, such as the strategy-RPG *Ogre Battle: The March of the Black Queen* (1993) and *The 7th Saga* (1993); and, finally, Capcom's *Breath of Fire* franchise also originated on this system with *Breath of Fire* (1993) and *Breath of Fire II* (1994).

Action and platform games were numerous, but some of the more recognized classics included Konami's *Super Castlevania IV* (1991), *Contra 3: The Alien Wars* (1992), and *Teenage Mutant Ninja Turtles IV: Turtles in Time* (1991) as well as Capcom's *Mega Man X* series. The total number of games released, give or take some for all territories, amounted to 535 in Europe, 720 in North America, and 1,440 in Japan. As with all platform title lists, the exact count depends on whether one includes special pack-in titles, altered rereleases, or combination and special-event cartridges, such as *Super Scope 6* (1992), *Donkey Kong Country Competition Cartridge* (1994), and *Super Mario All-Stars + Super Mario World* (1993). Eager fans have translated many of the Japan-exclusive games in recent years, particularly RPGs and games from known franchises, such as *Mystic Ark* (*The 7th Saga 2* [1995]) and *Seiken Densetsu 3* (*Secret of Mana 2* [1995]).

The console enjoys enduring popularity and is routinely hailed as one of the best consoles of all time. Nintendo released the SNES Classic in 2017, a

miniature replica emulation machine with twenty-one onboard games, including *Star Fox 2*, officially released for the first time. SNES games are also released in virtual consoles and online Nintendo stores for the Wii and the Switch, yielding access to the beloved classics to younger generations.

Supergiant Games

Supergiant Games is an independent game development studio based in San Francisco, California. Originally founded in San Jose by Electronic Arts (EA) Los Angeles veterans Amir Rao and Gavin Simons, Supergiant has grown to twenty employees and released four critically acclaimed games over the first ten years of its existence. Supergiant's games are noted for their emphasis on characters and story, their distinctive

visual style courtesy of art director Jen Zee, and their award-winning original scores written, produced, and performed by in-house composer Darren Korb.

Rao and Simons met while working on the *Command & Conquer* franchise at Electronic Arts' Los Angeles studio. In 2009, the pair decided to quit their jobs to work on a game of their own: an isometric action-adventure affair that would feature literal world-building (the world visibly comes into being as the player makes her way through it) and dynamic narration voiced by Logan Cunningham. That game turned out to be *Bastion* (2011), Supergiant's debut title that earned the fledgling studio several accolades, not the least of which a NAVGTR award for Cunningham's performance. Released for the Xbox Live Arcade as well as for the PC through Steam in the summer of 2011, *Bastion* sold over three million copies across all platforms by 2015 and was well received by consumers and critics alike.

Supergiant's sophomore effort, *Transistor* (2014), failed to improve upon its predecessor's reception but was a very successful release in its own right, selling over one million copies and earning over one hundred industry accolades, including nominations for Best Independent Game and Best Score/Soundtrack, a Game Developer's Choice Awards nomination for Best Audio, and a BAFTA nomination for Cunningham. Supergiant's next game, *Pyre* (2017), featured a rare mix of role-playing game (RPG) and sports game elements set within an original fantasy world. *Pyre*'s development was a time of experimentation for Supergiant. According to creative director Greg Kasavin, *Pyre* "didn't begin in some kind of document or pitch"

(Francis 2016). Rather, the final game was the result of an extensive prototyping phase.

As *Bastion* and *Transistor* had done before it, *Pyre* performed well despite (or perhaps because of) its idiosyncrasies and helped solidify Supergiant's reputation for quality presentation in both visuals and sound as well as narrative design. In December 2018, Supergiant Games unveiled its fourth title, *Hades*, as part of the launch of Epic Games' online distribution platform, the Epic Games Store. On top of marking the beginning of a relationship with a new distributor, *Hades* was Supergiant's first Early Access launch. In Kasavin's words,

We conceived of [Early Access] of this game as part of the whole package right from the start. . . . We think of the Early Access launch almost as a sort of pilot episode of a series or something like that, where it's a lot of setup, you meet a lot of the characters, and you figure out what the conflict is all about. But the resolution of the story is not all in the game yet, and we'll roll out new characters and more events in the story over the course of the Early Access period, along with just improving every other aspect of the game with any luck. (Francis 2019)

Clearly, Supergiant Games has already begun to make an impact on the world of video games.

Survival Horror Games

Survival horror is the well-known label given to scary video games. The horror genre's main objective is scaring the audience, and it has found an excellent niche in video games because fear has a strong action tendency and is clearly object oriented. A frightened person commonly chooses between freezing motionless with the hope of going unnoticed, fleeing from the danger, or fighting the threat; a novel reader or film viewer can only witness a character choosing between these alternatives, but the gamer is often forced to make such a choice. Consequently, early in its history, video games have maximized the potential of scary situations and scenarios. From *Haunted House* (1981) for the Atari VCS 2600 to the PC text adventure game *The Lurking Horror* (1987), from the adaptation of

Friday the 13th (1989) on the Nintendo Entertainment System (NES) to the multiple windows text-and-graphic adventure *Uninvited* (1986) for the Macintosh, and from *Project Firestart* (1989) for the Commodore 64 to *Sweet Home* (1989) for the Nintendo Famicom, gamers have found themselves plunged into typical horror stories, confronting the usual bestiary and evil of horror fiction.

Although early video games might have been considered frightening in their time, their depiction of horror was, if not textual, rather abstract with limited effects. By the 1990s, the technical capacities of home computers and home consoles (particularly the Sony PlayStation) had evolved enough to enable a *mise-en-scène* of fear similar to the horror film, raising the genre's popularity and identifying it specifically as *survival horror*. The term was coined for the Japanese game *Biohazard* (1996; known as *Resident Evil* overseas) for the Sony PlayStation. The formula, however, comes from both *Resident Evil* and the French game *Alone in the Dark* (1992) for the PC, which were in turn both inspired by George Romero's zombie movies.

Associated with the work of H. P. Lovecraft for commercial sake, *Alone in the Dark* was the first horror game to display three-dimensional polygonal characters and objects in two-dimensional pre-rendered backgrounds. The action is depicted from a variety of fixed camera angles that serve as much to conceal as to reveal the space of the game world. Choosing between two player characters (one of whom is the private detective Edward Carnby, who will become the main character in the subsequent four games of the series), gamers have to stay alive and escape from a mansion in which

they have been trapped. To do so, they need to find various helpful documents, manage a limited inventory and scarce resources, solve many puzzles, and fight zombies or other dreadful monsters.

Resident Evil follows the same framework as *Alone in the Dark* and has trapped two playable members of a Special Tactics and Rescue Squad in a mansion filled with zombies and various mutated creatures. The game called attention to the genre by welcoming the gamer to “the world of survival horror.” Played on the PlayStation, the game cannot be saved at any point; to save the progress, the gamer must find ink ribbons to be used in typewriters that are located in only a few rooms, adding to the tension. With more than twenty games, *Resident Evil* has become the most prolific horror series of all time (although not all of them are survival horror games).

Alone in the Dark and *Resident Evil* set the conventions of the genre. From a vid-eoludic perspective, survival horror games remain action-adventure games that develop a specific storyline that draws on common horror themes and is told through cutscenes as well as various written or audio documents. Although survival is the principal issue in a majority of video games, it is emphasized by the vulnerability of the player character who, without the gun power and the supply of ammunition found in shooting games, has to face or run away from monstrous foes while finding his way out of labyrinthine spaces, gathering various items, solving puzzles, and overcoming obstacles. Survival horror games are also notorious for their clumsy controls, which make the game even more difficult—for both combat and movement through the game world.

From a horror perspective, the genre is defined by the use of all the horror film tropes, such as an eerie atmosphere in dark or claustrophobic spaces. To take advantage of the camera work and montage, the games show the player character from a third-person perspective. Predefined camera angles transform the off-screen space into a blind one where monsters hide and one from which they can come out at any time to startle and to kill the player character. Sound is exploited to immerse the gamer in the horrific universe, enabling threats to be sensed, suspected, or anticipated through forewarnings of the coming monsters.

Like any genre, survival horror has changed and evolved. *Silent Hill* (1999) replaced pre-rendered realistic backgrounds with a real-time three-dimensional dark and foggy resort town. With a more psychological approach to horror that explores the tortured mind of the player character, and with more imaginative and subtle anticipatory fright, *Silent Hill* has expanded the domain of survival horror to one of terror (it could even be called *survival terror*). Two devices, a flashlight illuminating the way and a pocket radio emitting white noise when dangerous creatures are nearby, help to elevate the level of dread. Among the subsequent games in the series, *Silent Hill 2* (2001) is considered to be one of the landmarks of the genre.

Fatal Frame (2002; known as *Zero* in Japan and *Project Zero* in Europe) has carried on in the same vein. In a truly Japanese tradition, the player character is young girl who has to fight ghosts in a mansion. The originality of the game and series (of the four installments *Fatal Frame II: Crimson Butterfly* [2003] is considered the most accomplished) comes

from the weapon employed within the game; it is not with a gun but with a camera obscura that the gamer destroys the spirits, waiting for the ghosts to get as close as possible before pressing the trigger to cause the most damage. In *Siren* (2004; two other *Siren* games came out in 2006 and 2008), gamers play ten characters and use a sightjack system that enables them to see through the eyes of the zombie-like enemies and to learn how they move, with the aim of steering clear of them.

Avoidance and escape are at the core of games such as *Haunting Ground* (2005) and the *Clock Tower* series (1995–2003), in which young girls spend most of their time running away from assailants and hiding in various places until the threat is gone. In the former, the main protagonist, Fiona Belli, is helped by a dog, and in the latter, a panic meter needs to be tended, otherwise the player characters become difficult or even impossible to control. *Eternal Darkness: Sanity's Requiem* (2002) has a sanity meter that, once emptied, produces a range of disturbing effects: sounds of someone being tortured in another room, rooms turned upside down, a player character transformed into a zombie, a “disk error” message, and so on.

Games such as *Resident Evil 4* (2005), *Dead Space* (2009), *Resident Evil 5* (2009) and the more role-playing *Bloodborne* (2015) have come to be increasingly focused on action and on more accurate player character controls. As this trend emphasizing combat is moving away from the vulnerability and the fundamental notion of survival at the heart of the scary experience, another cluster of games have accentuated the need to flee.

Insofar as these games are more often played from a first- rather than a third-person perspective, we might say that they are not per se survival horror games. Yet, first-person perspective games have appeared since the beginning of the horror videoludic genre, starting with *3D Monster Maze* (1981), in which the gamer has to escape the lair of a Tyrannosaurus Rex before being devoured. Other first-person action-adventure games such as *Clive Barker's Undying* (2001), *Condemned: Criminal Origins* (2005) and *Call of Cthulhu: Dark Corners of the Earth* (2005) are notable also works. With the *Penumbra* Trilogy in 2007–8, and specifically with *Amnesia: The Dark Descent* in 2010, indie developer Fric-tional Games has demonstrated the terrifying feeling of not having any means to defend oneself. *Outlast* (2013) and *Alien: Isolation* (2014) have, among other games, relied on mechanics of flight rather than fight. The effect of the first-person perspective, erasing the distance between the point of view and the point of action of the player character, has been accentuated with the use of the virtual reality (VR) headset putting the gamer—that is, the point of interaction—right in the game world. The significance of this option has been underscored by *Resident Evil VII: Biohazard* (2017), the first full triple-A scary game sold for the PlayStation VR.

Similar to literature, comic books, and cinema, the horror genre in video games will always remain popular, regardless of the cycles of hipness. As we might have thought that the survival horror genre could become “living dead,” scary video games in general still embody and represent what is monstrous and what never dies.

Sustainability

Video games arose during the late 1960s and 1970s, around the same time as the growth of environmentalism, but their technological basis and digital and virtual nature did not make them likely candidates for involvement in the sustainability movement; therefore, it was some time before the two found a connection. Today, however, video games can be connected to the Green movement in two ways: through their form (because they consume energy) and through their content (which can be designed to teach and encourage Green ideas and practices).

As electronic devices that consume energy, home video game console systems should be turned off when not in use. A 2008 report from the Natural Resources Defense Council reported that many game consoles are left on continuously and that over 11 billion kilowatt hours a year of wasted energy, costing consuming over \$1 billion, could be saved by turning them off (Horowitz 2008). According to the report, among the three seventh-generation consoles, the Nintendo Wii uses the least energy at 16 watts, the Microsoft Xbox 360 uses 119 watts, and the Sony PlayStation 3 (PS3) uses 150 watts. Sony does feature an online update that helps power management in the system, and both the Xbox 360 and the PS3 have auto-shutdown

modes; however, these have to be enabled by the user.

Some companies designed their systems to be energy efficient. San Diego-based Zeebo Inc. produced the Zeebo console, which was aimed at consumers in emerging markets in Brazil, India, China, and Mexico. It used only one watt of power, making it by far the most power-efficient contemporary system. Packaging is another area where costs to the environment can be reduced. Pocket-watch Games' *Venture Arctic* (2007) is sold in "Go Green Packaging," which means 100 percent recycled materials and no plastic (Watson 2009). Like the music industry, some games companies have reduced the amount of packaging surrounding their products, and online distribution of games has eliminated the need for packaging altogether.

Games can also encourage the Green movement by teaching and embodying environmentalist ideas in an interactive, educational format. Some of the earliest games that could arguably be connected to the Green movement include *SimCity* (1989) and *SimEarth* (1990), which simulated environments and required players to manage resources to keep their cities and planets healthy. The design of *SimEarth* was even assisted by James Lovelock, author of the Gaia hypothesis, which looks at a planet's organic and inorganic elements as one big self-regulating system. Since then, a number of games have contained green themes, such as *Awesome Possum . . . Kicks Dr. Machino's Butt* (1993), in which players collect recyclable bottles and answer questions about the environment, and *Oddworld: Abe's Oddysee* (1997), which is about environmental destruction. One can also find green games that range from casual

games, such as Nintendo's *Chibi-Robo Park Patrol* (2007) and National Geographic's *Plan It Green* (2009), to serious games, such as the urban-planning simulator *IBM CityOne* (2010), Red Redemption's *Climate Challenge* (2006), and *Fate of the World* (2011). Other games, like the experimental game *Flower* (2009), evoke green themes in more subtle ways, causing players to consider the natural world and our effects on it.

There is a growing awareness of environmental issues within the video game industry. In March 2019, the Fourth UN Environment Assembly included a "Playing for the Planet" panel discussion, which reported that "87 per cent of the 50 leading gaming companies demonstrate a deep commitment to making a change and are willing to support further action on this issue" (UN Environment Programme 2019). On September 23, 2019, twenty-one of the largest video game companies gathered at the UN Headquarters in New York during the UN secretary-general's Climate Action Summit and formally committed to take action to help the environment. Together they launched the Playing for the Planet Alliance.

Sweden

The first Swedish digital games were developed for the first computers installed at Swedish universities in the 1950s. As employees at state-run universities in a Western democracy, Swedish researchers had good ties to the United States and could share their inventions with developers overseas. Digital games were also created by the first Swedish computer manufacturers, such as DataSaab. These games were a fun distraction for engineers and scientists, but they were also utilized as a way to showcase the abstract capabilities of these early computers. Later in the 1970s, as games became more widespread, Swedish home electronics company Luxor produced Channel F consoles on a license from the American company Fairchild, but no games were developed especially for the Swedish domestic market.

A new generation of dedicated game developers emerged with the introduction of home computers in the late 1970s and early 1980s. Home computers meant a dramatic dispersion of the essential technology for game development. Outside the core hardware development

countries, the United States and Japan, and with no Nordic electronics companies successfully venturing into computer or console manufacturing, home computers became a gateway for the establishment of a Swedish game industry. However, the first Swedish developers did not establish lasting companies in the still young and rapidly evolving market. Some of the developers were absorbed into the more mature British game industry that had been established alongside the early British computer industry. Swedish developer Bo Jangeborg moved to the United Kingdom and developed *Fairlight* (1985) and *Fairlight II* (1986) for British publisher the Edge Software. Jangeborg and other early developers eventually found other opportunities in the fast-growing software industry and left game development.

However, since the end of the 1980s and early 1990s, there has been an active and expanding game development industry in Sweden. A new generation of companies started out during this phase. Several had ties to the tech subculture surrounding the demoscenes. Companies such as Digital Illusions, Starbreeze, Unique Development Studios (UDS), Atod, Southend Interactive, and O3 Games all had their roots in different demo groups. The transition from amateur to commercial game development was not always straightforward, but the tech-savvy young developers had talent and an affinity for developing advanced computer games. One of the most successful Swedish companies, Digital Illusions (later DICE), started out from a demo group and eventually developed the innovative pinball game *Pinball Dreams* (1992) for the Amiga 500. The company later developed a number of

racing games, but the true economic success came after the acquisition of the company Refraction Games and the subsequent venture into first-person shooter (FPS) games. The many *Battlefield* games have been the company's core game series.

The industry expanded rapidly during the dot-com bubble years at the end of the 1990s and up until 2001 and again from 2004 until the financial crisis around 2008. However, many companies had a rough time finding viable publishing contracts, and many were struggling with their profitability. One of the largest Swedish companies, Grin, failed in 2009.

The broader economic success of the Swedish game industry came with the new disruptive technologies of digital distribution and smartphones. A number of Swedish companies were able to utilize the new possibilities surrounding platforms such as Steam and iPhone or Android phones. The company King successfully entered the newly vitalized mobile phone market with the game *Candy Crush* (2012). Starbreeze had developed the critically acclaimed game *Chronicles of Riddick: Escape from Butcher Bay* (2004) but had larger economic success from extending the life span of its heist game *Payday 2* (2013) by using upgrades and selling multiple DLCs (downloadable content). However, the most striking Swedish success has probably been Mojang and its game *Minecraft* (2011). The company successfully used an early access business model. The game was not only a broad economic success but also became a global phenomenon with a large community, and influenced whole markets adjacent to gaming, such as online streaming. Mojang was sold to Microsoft in 2014.

Several of the larger successful Swedish companies have been acquired in the same way by larger global game publishing companies and are no longer Swedish owned; DICE, King, Massive Entertainment, and MachineGames are owned by American or French multinational publishing corporations.

A wide ecosystem of smaller independent game developers producing a wide range of successful and acclaimed games have also developed alongside the larger Swedish companies. Coffee Stain Studios has developed the open-ended action game *Goat Simulator* (2014), Frictional Games developed the horror game *Amnesia: The Dark Descent* (2010), Arrowhead Game Studios developed the action-adventure *Magicka* (2011), Denaton Games developed the ferocious top-down shooter *Hotline Miami* (2012), and Niffilas has developed a number of visually noteworthy 2-D adventure games, such as *Knytt* (2006) and *Night-Sky* (2011). With numerous other game developers, the Swedish game industry has established itself as one of the more prominent in Europe.

Switzerland

The history of video game hardware and software in Switzerland mainly began in the context of universities. In 1976, at the Swiss Federal Institute of Technology in Lausanne (EPFL), Jean-Daniel Nicoud and his team built twenty units of the Smaky 4 model, the first Swiss made microcomputer, with financial help from the Swiss Federal Institute of Technology in Zurich (ETH-Zürich) and Digital Equipment Corporation, an American company. In February 1978, EPSITEC-system SA was founded with Cathi Nicoud at its head to sell the Smaky 6 model. The "Smaky" line (for SMArt KeYboard) was mainly aimed at schools from the French-speaking part of the country and thus included mostly educational computer software. Later, the Smaky line required a dedicated catalog of games, which led to the creation of the *Blupi* series (also known as *Eggbert* in the United States), mainly developed by Daniel Roux: *Toto à la maison* (1988), *Toto s'amuse* (1990), *Blupi Explorateur* (1993), *Blupimania* (1994), *Planet Blupi* (1997), *Speedy Blupi* (1998), *Blupi s'amuse* (2000), *Speedy Blupi II* (2001), and *Blupimania II* (2003). Following EPSITEC's design approach of considering video games as learning tools, Daniel Roux also created *CoLoBoT* (2001) and *Ceebot* (2002), two games meant to teach programming basics, and *Buzzing Cars* (2002).

Further north, in the German-speaking part of the country, some individuals from the Amiga enthusiasts and hackers scene had decided to develop their own games by the end of the 1980s. They worked mainly with LinEL, a Swiss publisher of both original games and ports on the Amiga line of personal computers.

This led to an important Amiga-focused lineup of Swiss games, among which one can find *War Heli* (1987), *Ball Raider* (1987), *Crack* (1988), *Dugger* (1988), *Leonardo* (1989), *Clown'O'Mania* (1989), *Pamehta* (1989), *Antares* (1990), *Rolling Ronny* (1991), *The Game of Life* (1991), *Züri* (1992), *Traps'n'Treasures* (1993), and *Starbirds* (1996). Developed by Roman Werner, *Traps'n'Treasures* is the most remarkable of all, first and foremost because of its technical qualities and creative design but also due to complicated relations with the German editor Starbyte Software, which made the game become a rarity sought by collectors. The point-and-click adventure game *Züri* (1992) is also noteworthy in that it includes the Swiss city of Zurich for its realistic setting.

The Smaky line and EPFL aside, the Swiss Federal Institute of Technology in Zurich (ETH-Zürich) gave birth to one of Switzerland's most original projects. *The Last Eichhof* (1993) released on MS-DOS by an independent small group of students, Alpha Helix, is a freeware and open-source vertical shooter meant as a criticism of the standardization of the Swiss beer market that was threatening independent microbreweries like Eichhof, in Luzern. The player controls a spaceship shaped like an Eichhof bottle and fights against an evil empire of international beer brands. The group continued their game design activities on MS-DOS with the vertical shooter game *Ravage* (1996), this time with a less unconventional approach to the genre.

In terms of revenues, the *Farming Simulator* series by GIANTS Software, which started with *Farming Simulator 2008* (2008), constitutes Switzerland's

most noticeable international economic success. The same know-how involved in designing successful, detailed, and factual simulation games was later observed in both *Train Fever* (2014) and *Transport Fever* (2016) by Urban Games.

Starting in 2010, Switzerland witnessed an accelerating shift from a fragmented and invisible game development scene to a connected, sustainable, benevolent, and expanding local industry. This was spearheaded by the support of Pro Helvetia, a state-funded public foundation, as well as many individual voluntary actions. The 2010s saw the artistic and institutional legitimization of the video game medium, illustrated by museum exhibits (La Maison d'Ailleurs, Aarau City Museum), festivals (Ludicious, GameZfestival, Numerik Games), and public workshops (Swiss Game Academy). During this period, many critically acclaimed Swiss games were released, which include *Moonga* (2010) by Everdreamsoft, *Dreii* (2013) by Etter Studio, *First Strike* (2013) by Blindflug Studios, *The Firm* (2014) by Sunnyside Games, *Feist* (2015) by Bits & Beasts, *Opticale* (2016) by Furinkazan, *Niche: A Genetics Survival Game* (2016) by Stray Fawn Studio, *Octahedron* (2018) by Demimonde Games, *Airships: Conquer the Skies* (2018) by David Stark, *Oniri Islands* (2018) by Tourmaline, and *Far: Lone Sails* (2018) by Okomotive.

Another example of the stabilization of the Swiss video game industry is the creation of the Swiss Game Developers Association (SGDA), whose mission is to represent the interests and voices of game developers in both political and cultural debates. Their work, in collaboration with national councillor Jacqueline Fehr,

led to the March 2018 release of an official report by the Federal Council—the head of government and state in Switzerland—validating the cultural and economic potential of video games.

Four national languages and five bordering countries are unique elements that define Swiss culture, with diversity at its core. The geographical position of Switzerland, along with its cultural and linguistic diversity, stable economy, and strong academic infrastructures, makes it a land of promise and potential in terms of game design. If linguistic and cultural barriers hinder the production of narrative-based games, they invite game designers to break them down, emphasizing interactivity and visuals in minimalist designs.

Syria

The bloody civil war that began in 2010 and the resultant exodus of refugees will always overshadow the fact that Syria was the cradle of video game development in the Middle East. In September 2000, *Under Ash*, a PC-based first-person shooter (FPS) game, was previewed to the public at a Damascus book fair, and it was considered to be the first commercial video game in the Middle East based on the Palestinian conflict. Created by Radwan Kasmiya and published by Dar Al-Fikr in 2002, *Under Ash* targeted Arab gamers, did not contain English subtitles, and was never sold outside the region (although limited copies found their way to Europe unofficially). The game received a lot of praise and managed to sell more than one hundred thousand units within the first six months of release—a considerable quantity, even compared with internationally best-selling titles’ sales in Middle Eastern markets. The success of the game naturally led to a sequel, and so Afkar Media was established and became the first independent game studio in the region.

During that time, another Syrian company, Techniat3D, developed *Zoya: A Warrior from Palmyra* (2002), an adventure game inspired by the *Tomb Raider* series. Sadly, the game sold fewer than a hundred copies in the region, and many claimed that the “improper attire” of the female warrior featured on the cover was the reason players avoided the

game. A revised version was made by Afkar Media, and the game was rereleased as *Victory Castle*; however, this version did not meet with much success either, selling just over a thousand copies. Consequently, Techniat3D was closed down in 2003.

Two years later, *Under Ash II* (also known as *Under Siege*) was released in 2004 but did not hit the retail shelves until late 2005 because the publisher was trying hard to access new markets with little experience in simultaneous releases. *Under Ash II* was positively received because of its realistic storyline, advanced graphics, and artificial intelligence (AI) for the time. The game has been described as a “docugame” because all the levels are based on actual events documented by the United Nations’ records from 1978 to 2004. This time around, the game also supported English subtitles.

The publisher decided to split the game into two parts to graze more money from enthusiastic gamers, so it released *Under Siege: Path to Freedom* and *Under Siege: Remnant of Human*. That said, the English version of the game, *Under Siege: Golden Edition*, was finally released in 2008; a strange tactic that was repeated later with *Quraish* (2005), the first Arabic real-time strategy (RTS) game, also developed by Afkar Media. *Quraish* was highly anticipated by Arab gamers because it was based on actual historical (conquest) wars during the early Islamic periods, a highly revered period in the region. The game was finally released commercially in 2008, after spreading its four campaigns on four independent package designs and one “Golden Version” with all the features.

In 2007, Spacetoan Media Group, a major kids’ satellite channel in the Middle East, invested in a new studio to localize Chinese role-playing games (RPGs), and Game Power 7 was founded with a front office in Dubai and a production facility in Syria, where they introduced an Arabic version of *Rappelz* (2017), the first online Arabic localized game. Successful operation and deep localization were major factors that allowed this game to enjoy nearly one million registered users.

In 2008, the Syrian company JoyBox was established, focusing on the casual games and mobile games markets. It has produced many types of games, ranging from two-dimensional arcade-style games that are basically sold to Al-Majd (a local Quiz TV channel) to three-dimensional prototypes of adventure games and racing games.

Starting in 2009, after the global financial crunch and eight years of civil war, most Syrian studios were either closed or had to change their business models toward training or outsourcing. *Road to Jerusalem* (2009), a comedy/adventure computer game published by Fares al Ghad, was the last production of Afkar Media before political unrest forced most studios and their talent to leave the country and create the next generation of video games from the diaspora.

T

Television

Television receivers, more commonly simply referred to as TVs, have historically been used to receive broadcast, cable, and broadband programmed content, but television plays a key role in the history and culture of video games as well. Early video game innovator and inventor Ralph Baer was inspired to begin work on the first commercial home video game system because of the lack of compelling television programming available. Baer thought the technology could be used to do more and in more innovative ways. In this way, television gave rise to home video games, and it still remains a common venue for video games. Television also shares its technological structure with the infrastructure of arcade video games: the cathode-ray tube (CRT). Whether sunk into a wood-grained home case made to look like living room furniture or encased in a futuristic fiberglass cabinet (e.g., *Computer Space* [1971]), both television and video games rely on video technology and, historically, CRTs as the basis for their display of images.

Using standard audio and video connector cables, so-called console video game systems are designed to connect with television sets and must be played in some proximity to the television itself so that the handheld game controllers can connect physically or via wireless connection to the system and back to the television. This puts the gamer and

gameplay in a limited physical space that is often defined by the placement of the television in a room. The advertising and press kits accompanying game systems—from the Atari VCS 2600 to the Nintendo Wii and the Microsoft Xbox Kinect—often promote the space around the television set as a zone for the shared familial pleasures of multiplayer gaming. As an “electronic hearth,” like radio before it, television inscribes video games into the domestic space of the home. Recent systems, from the Xbox on, include interface components that allow gamers to switch easily between passive television programming, films, and gaming content. Some television programs even adapted games as narrative content, such as *Pac-Man: The Animated Series* (1982–83) and the *Super Mario Bros. Super Show!* (1989–91). Of course game adaptations of television programs are also common, especially games based on children’s programming, such as *Dora the Explorer: Journey to the Purple Planet* (2005) and *SpongeBob SquarePants: Creature from the Krusty Krab* (2006). Adult-themed game adaptations of television programs run the gamut from *Home Improvement: Power Tool Pursuit* (1994) to *Buffy the Vampire Slayer* (2002) and *The X-Files: Resist or Serve* (2004).

With the expansion and convergence of screened entertainment in recent years, there are now serial programs about gaming culture developed online that have also been shown on television and released on DVD, such as the

MMO-skewering program *The Guild* (2007–13). Gaming structures, strategies, and scenarios are now commonplace in narrative television, with series like *Black Mirror* (2011–present) delving into the darker depths of gaming in episodic anthologies (see *Black Mirror* episodes “Playtest” [2016], “San Junipero” [2016], and “U.S.S. Callister” [2017] and the interactive feature “Bandersnatch” [2018]). *Black Mirror*’s “U.S.S. Callister” uses the premise of a contemporary game development company and its massively multiplayer online (MMO) game to simultaneously critique the culture of classic *Star Trek* television episodes. As this transposition of content across forms reveals, the shared space of the television screen has led to two distinct but complementary forms of entertainment. Increasingly, “television” is a reference point for understanding media across an environment of screened media, including computers, laptops, mobile phones, watches, and more. The television is no longer a specific device: it is an interface for understanding screens. Gaming and programming are two dominant ways to engage with television.

Despite all of these technological and cultural connections between video games and television, video games remain overlooked within the academic field of television studies, which focuses on television programming and industry rather than pursuing, like Baer, other uses of television for interactive entertainment. Recent work by video game scholars offers a corrective in this regard, resituating television in the history of video games as a crucial part of the video game system apparatus that includes game hardware, software, controllers, and audio and video elements. These last

two, audio and video, are provided by the television set (possibly with the addition of ancillary sound systems incorporated into the setup as gaming systems and sound became more complex). Although home computer games are often reliant on a high-quality video card as part of a computer system, console-based home video games instead work with and on television’s graphic capabilities. TV’s influence in this regard is tremendous, from video game designers working with the graphic limitations of game hardware and 1970s television sets to design games that produced compelling graphics despite extreme technological constraints to the emergence of games designed to maximize the high-definition pleasures of contemporary television screens and the home theater audio systems that often accompany them.

Tempest

Tempest is a coin-operated arcade game designed by Dave Theurer and released by Atari in October 1981. Theurer also designed the arcade games *Missile Command* (1980) and *I, Robot* (1984), among

others. *Tempest* is a shooting game that features abstract three-dimensional vector graphics. Both *Tempest* and its cabinet art pick up on late twentieth-century popular anxieties related to alien invasion and the perpetual threat of technologically driven annihilation. Play occurs sequentially and repetitively through different “tubes,” or playfields, increasing in difficulty over the course of the game’s ninety-nine levels. There are sixteen different tube layouts, and these layouts are designed to evoke the sensation of peering into a geometrically outlined void (such as a circle, triangle, or plane). There are five types of enemies—Flippers, Tankers, Spikers, Fuseballs, and Pulsars—and each has its own distinct visual style and threat behavior. Enemies may be destroyed by a single shot from the player’s avatar (the “shooter”) or by the Superzapper, a limited use weapon capable of destroying all on-screen enemies at once.

Tempest’s eye-catching imagery and fast-paced play were enabled by its Wells-Gardner Color X-Y Display vector monitor, and *Tempest* was the first arcade machine in the Atari line to include this technology. *Tempest* is also notable for its Skill-Step play system and Operator-Information Display. The Skill-Step play system is a precursor to the now omnipresent feature in video games of user-selectable difficulty, whereby the user determines a game’s level of challenge prior to play (in *Tempest*, the player is able to begin at tube 1, 3, 5, 7, 9, or 11, according to preference). The Operator-Information Display is similarly prefigurative, tracking a variety of metadata, including average game time and total number of games played. Such data about gameplay have become

staples in modern gaming, with collected information used by developers to refine design elements and prompt play by describing performance to the player as part of the game experience (such as displaying hit percentage, level completion time, enemy destruction, and so forth).

Tempest’s iconography has been referenced in media of all types—from video games (e.g., *Space Giraffe* [2007]), to movies (e.g., *Night of the Comet* [1984]), to television shows (e.g., *The Simpsons* [2006])—and the game has been regularly rereleased in anthologies (e.g., *Atari Arcade Hits: Volume 1* [1999]) in the decades since its development. It is considered a landmark game by many game designers, players, and critics.

Temporal Navigation. See Navigation (Temporal)

Tencent Holdings Ltd.

Tencent Holdings is the largest tech, digital, and social media platform company in China with its value reaching USD 522 billion, a value that surpassed Facebook

(USD 519 billion) in 2017. Tencent owns the two largest social media platforms, or apps, in China, namely WeChat (1 billion monthly active users as of October 2018) and QQ (669.8 million users as of December 2018) (CIW Team 2018). With WeChat evolving into a multipurpose platform (Montag, Becker, and Gan 2018), covering the function of social media, payment, gaming, shopping, taxi ordering and finance, Tencent has been integrated into the daily life of the population, with more than one billion Chinese users; its content is highly censored and monitored by the Chinese government (Harwit 2016).

For a mixed purpose of propaganda, social control, and public relations, different departments and units of the government also set up official accounts on WeChat to influence public opinion. Despite the fact that WeChat drives lifestyle spending, with an estimate of USD 1.76 billion annually, and that it also carries advertising, as of 2017, Tencent's revenues still largely rely not on social media but video games, which account for 40 percent of its revenues. As one of the largest game companies in the world, with an annual revenue of RMB 237.76 billion (USD 21.9 billion) (Futter 2018; Statistia 2018), Tencent has become a major entertainment hub inside China. Outside China, where it is usually regarded as a form of China's soft power, Tencent also acquired major game companies, including Riot Games, which owns *League of Legends* (2009). On one hand, Tencent is powerful in terms of social influence, and this sometimes explains why the authorities also depend on Tencent for expanding their governance and influence. On the other hand, its finances are highly contingent on the

popularity of the entertainment business, the content of which is constantly regulated by the Ministry of Culture. But the policies of the latter vary over time.

At the end of 2018, under the general banner of "over entertaining," which legitimizes the banning of sensational, immoral, and obscene media and online content for a period of six months, the State Administration of Press, Publications, Radio, Television, and Film ceased issuing licenses for new video games. As a result, Tencent suffered from an estimated loss of USD 200 billion in the game market during this period (Chan 2018). In general, Tencent exemplifies the operation of the content and creative industries in China: the state allows only a few players so that they are also guaranteed substantial profit, but they have to align with the state's interest in terms of content and the public discourse generated.

Tetris

The falling block puzzle game known as *Tetris*, which is world famous for its simple but addictive gameplay, is among the most popular games ever released. Around 1984, Alexey Pajitnov, a computer engineer from the Computer Center of the Russian Academy of Sciences, developed the game on an Elektronika 60 terminal computer. His colleague Dmitry Pavlovsky assisted him, and Vadim Gerasimov, a teenage student at the time, ported the game to the IBM PC. From there, a PC version burst into popularity and began spreading around Moscow and then Western Europe.

At the time, *Tetris* was not patented. In the former Soviet Union, intellectual property rights were not established for private individuals, and private business

was prohibited. This situation eventually generated considerable profits for various businesses and people, which caused a number of conflicts. In 1986, before any legal rights were established, Spectrum HoloByte released an IBM PC version of *Tetris* in the United States. Its license was obtained from a London publisher, Andromeda, who was licensing rights that were unofficially acquired by Novotrade, a company from Budapest. Other versions also flourished before 1988, when the Soviet government began to market the *Tetris* trademark and granted Pajitnov paternity over it. A year later, licenses were signed over to Atari, for the arcade version, and to Nintendo, who soon bundled *Tetris* with every Nintendo Game Boy console.

Up until 1996, Pajitnov had made almost no money from the game, despite Nintendo’s commercial success with it. Because of the nature of communism, Pajitnov had to wait until the rights were fully returned to him from the Russian state to collect money for his achievement. Today, the Tetris Company cofounded by Pajitnov owns the trademark and maintains the “Tetris guidelines.” It standardizes basic parameters, such as the size of the playfield and the control keys and the hues, which vary from monochrome or grayscale graphics to several colors for each of the distinct shapes present in the game.

Tetris’s seven game pieces are tetrominoes, each composed of four adjoining squares arranged in a different way; the game’s name comes from combining the words *tetromino* and *tennis* (even though it sounded somewhat strange in Russian, Pajitnov insisted on it). The seven tetrominoes are identified by their shapes:

A boy plays a version of *Tetris* on a tablet computer. (Vladimir Stanišić/Dreamstime.com)

O or square, J or leftgun, L or rightgun, I or dash, Z or leftsnake, S or rightsnake, and T or tee.

Tetris's core gameplay involves rotating the falling tetrominoes and fitting them together in rows. Points are awarded when rows are completed, and completed rows disappear, allowing the other rows to drop down and giving the player more room to manipulate the falling tetrominoes. The tetrominoes enter from the center of the upper boundary of a rectangular grid ten bricks wide by twenty bricks high. Some versions of the game feature a window showing what kind of piece will appear next, allowing players to anticipate what moves to perform. Each tetromino can be pivoted in ninety-degree increments, translated horizontally, or "dropped" hastily. As players react by reorienting falling pieces in search of the best positioning, they mentally

represent the shapes using both mental rotation skills and spatial visualization skills, both of which improve over time.

The game's difficulty results from the pieces piling up as well as the increasing rate at which they fall, both of which reduce the amount of time the player has to manipulate and position the pieces. Although every piece can complete one or two rows when it is the last to be added to a row, the I, J, and L pieces, which all have at least three blocks in alignment, are able to clear three rows. Only the I tetromino is capable of clearing four lines simultaneously, and this action is referred to as a *tetris*. Many versions of the game also award additional points based on the height and speed of the falling piece.

When a finished row disappears, the stacks above it cascade and fill the newly created negative space as well as other possible openings under it.

Traditional versions of the game move the piles of blocks down by a distance equal to the exact height of the cleared lines below them, and rows often must be cleared to reach the unfilled gaps beneath them.

The player's objective is to maximize the number of points gained over the course of the game. Doing so requires clearing as many rows as possible to open the way for the never-ending fall of new blocks and to avoid running out of space vertically. When this happens, it is the end of the game, known as *topping out*.

Frequently hailed as one the best video games of all time as well as the most ported in the history of video gaming, *Tetris* has also been the focus of documentaries and a prevalent subject in academic research. Vladimir Pokhilko, a friend of Pajitnov, was the first clinical psychologist to conduct experiments using the game, only a few years after its creation. Since then, it has been used in several fields, including the theory of computation, the algorithmic theory of games, and cognitive psychology. It is also a widely used example in new media and game studies, where different readings of *Tetris* also gave birth to a classic conflict between simulation and narrative. Gonzalo Frasca sees the game as entirely nonrepresentative, an abstract environment where players test their skills (Frasca 2001). In contrast, Janet Murray sees a specific narrative: "a perfect enactment of the overtaken lives of Americans in the 1990s" (Murray 1997). However, according to Marie-Laure Ryan, that narrativity is of the lowest degree because it is "hardly interpretable as the pursuit of human

interests in a concrete situation" (Ryan 2001).

Text Adventure Games

Text adventure games (also text games or text-based games) are video games known for their minimal requirements of computer processing and storage due to the exclusive usage of text characters in their presentation of rules and universe (through written descriptions or ASCII art). Today, this genre also encompasses hyperlink or multiple-choice fictions that can be found on the internet. The concept behind the genre is to present players with textual content that provides an idea of their surroundings and is scattered with accentuated keywords to be used during the game experience and toward which they are invited to express action commands to interact with the created world.

Text adventure games contain a narrative framed within a theme (occasionally based on popular franchises) and a main character, controlled by the player, who must fulfill a specific role in the story. Armed with this information, players have a better grasp of the actions they can perform in the game, thus helping the illusion of total freedom that is proposed by the open text entry field generally used as an interactive interface in this type of software. Most text adventure games use algorithms with databases to allow for word or choice

recognition during communication with the player, and many also use a parser to analyze basic sentence structure. The function of these systems is to interpret the player's words and express their consequences by displaying them using dramaturgical tones. Most commonly made to make players aware of their current state, the game results will furthermore be modified according to different diegetic contexts. One of the obstacles to this human-machine communication is its reliance on very specific vocabulary (sometimes listed in a help file) that often creates gaps between the level of language that is asked of players (verb-noun combination) and the one used in return to players' requests (correct or even literary).

The common factors in the games of this genre reside in their presentation (as the genre's name would have it) and the requirement for players to complete some form of puzzle, with or without random factors, to reveal and explore the storyline. Some text adventure games, typically called *interactive fiction*, principally place their focus on the literary content of their proposition, reducing the importance of puzzle completion for the unveiling of the story. Comparable to novels, these games are often recognized as a separate category with greatly detailed character depictions and realistic dialogue, whereas the others use more advanced gameplay with complex interface elements, such as blinking words, colors, interactive maps, and scoring, among others. At their core, much as is the case for books, interactive fiction relies on immersion through the way a story is conveyed and a world is described, which encouraged the production of well-written games such as *Trinity*

(1986) and *Varicella* (1999). As for other text adventure games, some would argue that their immersion is mainly challenge based, sometimes to the point of giving the genre a reputation for being of an utmost difficulty (partly because of unforgiving and unpredictable consequences that can be experienced in such titles as *Planetfall* (1983) or *Hitchhiker's Guide to the Galaxy* (1984), both of which are purposefully misleading and threaten the player with restarting the entire game as a result of failure or the simple misunderstanding of the events).

Using mostly their imagination, players might also require the use of notes and visual mapping tools for their exploration and recollection of keywords during the many side scenarios and humorous events planned by the author. Acquiring knowledge and remembering the world are the phenomena on which text adventure games base their concept of freedom of action and sense of immersion. Online multiplayer versions of text adventure games, called MUDs (multiuser dungeons [or dimensions or domains], occasionally referred to as *interactive realities*), such as *Gemstone* (1988), *Darker Realms* (1990), or the original game *MUD* (1978), are also built to facilitate a sense of belonging through more natural conversations and exchanges between players, following the same general graphical context as their predecessors, but combining elements of many other different genres of video games, such as role-playing or hack-and-slash.

HISTORY

Before the support of computer graphics, game designers were forced to get creative and sketch their worlds only from

green or orange letters on dark monitors, either through written descriptions or by constructing representations using only letters and symbols from the ASCII character set (as in *Rogue* [1980], from which the video game subgenre *rogue-like* originated). As an answer to this situation, text adventure games first appeared as a way for role players to share with others their tabletop role-playing game experiences by programming a computer-controlled “dungeon master” (with references to *Dungeon & Dragons* (1974), mainly inspired by fantasy universes). In 1976, *Colossal Cave Adventure* was designed by spelunker Will Crowther and became the game generally recognized as the origin of the genre, despite Peter Langston's mainframe games *Wander* (1974) and *Castle* (1974), which fell into obscurity until their rediscovery in the 2010s. *Colossal Cave Adventure* would be extended by Don Woods to become *Adventure* (1976), which quickly spread, spawning the text adventure game genre.

The most commercially successful interactive fiction of this time was Infocom's *Zork* (1977), which had multiple rereleases and sequels through 1986. In 1978, with the explosion of the personal computer market, text adventure games became widely published and marketed (through magazines and mail services), starting with Scott Adams's *Adventureland* (1978). These games introduced many influential video game features, such as mailed-to-home games (*Adventure International*, 1978), bonus material (e.g., sunglasses, game codes, and invisible ink booklets called InvisiClues by Infocom [1984]), packaging, narrator characters, and cliff-hangers teasing upcoming sequels (all originating from the passage of *Zork* to *Zork II* [1981]).

Later on, with graphics becoming a viable option, many text adventure designers included visual support, sometimes without considering whether it was necessary or what consequences it would have on the genre. Starting with Roberta Williams's *Mystery House* (1980), text adventures with graphics appeared, and games such as Sierra Entertainment's *King's Quest* (1984) became popular. This evolution continued until text was gradually subsumed into the diegesis (in the manner of books offering in-game lore for *Myst* [1993]) or were solely used for character dialogue interaction (as used in *Maniac Mansion* [1987]), slowly becoming the genre of point-and-click games that is most common today (as can be seen with the evolution of the aforementioned *King's Quest* series from 1984 to 2015).

Despite this, text adventure games expanded to a variety of other platforms and markets through the years. They were sold in bookstores, fused with chat room services for their gamification, were hidden inside other software as Easter eggs (e.g., the text adventure game within the Google search engine developer's console or the adapted version of *Dunnet* (1982) that can be found in the Terminal of every MacOS), and became the object of communities (e.g., Textadventures.co.uk and Interactive Fiction Database [IFDB]) and fan clubs that ported these games (through emulation systems such as the Z-machine, developed by Infocom in 1979) on mobile applications, websites, and different hardware supporting the format (such as *Dark Mage* (2003), which was originally made for the Atari 2600 but was adapted in 2004 for the TI-83 graphic calculator).

That said, the movement for new text adventure games never entirely disappeared. On platforms such as Kickstarter and Steam, inspired developers are raising interest in the genre once again, drawing from new features, such as reactive visual surrounding environment (as seen in *The House Abandon* [2016]), episodic narrative, animated puzzles (as shown in *Code 7* [2017]), sound effects, music soundtracks, and voiced narrative (as can be experienced in *The Lost Legends of Redwall: Escape the Gloomer* [2018]). Additionally, nostalgia being one of the main factors in this revival, the minimal requirements of processing and storage is allowing adaptations to e-book readers and tablets and profits from a new category of casual gamers participating in interactive fiction as a newfound interest. The free open market of e-book publishing has also inspired communities of hobbyists to produce a profusion of tools (e.g., Twine and Inklewriter) that allow anyone to create such games for competitions, interactive media exhibits, in honor of their favorite franchise, or simply for their personal pleasure.

The genre of text adventure games has shown a great amount of resilience over the years with its possibilities of adaptation and accessibility, its low material requirements and open-endedness, its simplicity while being challenging, and, of course, its nostalgic attributes, which tend to indicate its predisposition for survival over time. Throughout forums and blog posts, a new portrait of text adventure games can be drawn. Multiple contexts show an interest and potential for the integration of the genre into tools and environments of different circles, from classrooms (as demonstrated by the website of Studio Code) to traditional

media companions (such as *Interstellar* [2015]). In parallel, more intelligent parsers are being tested, and machine learning's capacity for language and decision making are developing, ultimately aiming to accomplish a more complete and natural communication experience, possibly tracing the arrival of a new important subgenre: spoken-word games (paired with and transformed as interactive audiobooks by personal assistant technologies such as Google Home, Siri, and Alexa). In the years to come, it would be reasonable to expect text adventure games composed essentially of computer-generated storytelling algorithms to be all around us, therefore mimicking and demonstrating the needs and roles of the "dungeon masters" that first gave birth to the genre.

Thailand

In 2018, Newzoo's 2018 Global Games Market Report ranked the Thailand market as twentieth by game revenues. The market is expected to top USD 2 billion (66.2 billion baht) in 2025, up from USD 597 million in 2017, sustaining an average yearly growth of 15 percent. In 2017, Thailand had 28 million gamers, and 1.2 million of them are hardcore gamers. There are also thousands of esports gamers. In 2017, the market for mobile gaming topped USD 46.1 billion, and the total revenue generated by the ten top-grossing iOS and Google Play games grew 85 percent year over year. The PC gaming market is expected to account for 15–20 percent of the Thai video game market in 2017, up from 6 percent last year. The surge in market share was fueled by competition among computer makers, driving down the price of gaming computers. The average gaming notebook, formerly selling in the upper 30,000 baht range, now goes for under 25,000 baht.

HISTORY

The history of video games in Thailand includes arcade games, console-based games, PC and LAN games, and online games. Arcade games have been imported into Thailand from Japan since 1993 by the Galaxy Group Thailand Company. Console-based games have existed since Atari launched the Atari VCS 2600 home console system in Thailand in 1977. The Super Nintendo Entertainment System (SNES) (also known as the Super Famicom) was very popular in Thailand because Nintendo provided additional devices, such as the Nintendo

Super Scope and the Power Glove, and had a wide range of games available, such as *Final Fantasy II* (1988), *Final Fight* (1989), *Super Mario World* (1990), *NBA All-Star Challenge* (1992), and *Dragon Ball Z: Super Butōden* (1993); players could play pirated copies of these games on 3.5-inch diskettes by using “Pro” devices. The Sony PlayStation was very popular because of its graphics and the pirated CD-ROMs of the systems’ games that were sold in Thailand.

The 2000s were a time of warring next-generation console systems after three big companies released their new systems: the Sony PlayStation 2, launched on March 4, 2000; the Microsoft Xbox, launched in the United States on November 15, 2001; and the Nintendo GameCube, launched on September 14, 2001. Finally, PC and LAN games such as *Warcraft: Orcs & Humans* (1994), *Command & Conquer* (1995), *Diablo* (1996), and *StarCraft* (1998) attracted many Thai gamers. Online games, such as Gravity’s *Ragnarok Online* (2002) from Korea, which was sold by Asiasoft Thailand, were also very popular.

THE VDO (VIDEO) GAME INDUSTRY IN THAILAND

Today, due to the progress of computer technology, the internet, and Thai education, some Thai game players have become game developers and started their own companies. Debuz, TumGame Company Limited, Samart Corporation, Play Thai, and AIM Advance are examples of such new companies. A games market is growing, and educational programs of game development are now offered in some Thai universities, such as Mahidol University, King Mongkut’s

University of Technology Thonburi, and Sripatum University. Also, the Software Industry Promotion Agency (Public Organization) (SIPA), now called the Digital Economy Promotion Agency (DEPA), is a Thai government agency that promotes and supports the development and marketing of software and digital content. The Thai Game Software Industry Association encourages Thai game companies to work together to share knowledge and experience and gain negotiating power.

PROBLEMS AND OBSTACLES

Video game development in Thailand faces three main problems or obstacles. As it is now the age of online games, the infrastructure of information and communication technology (ICT), often used as an indicator of a country’s competitiveness, is used for ranking by the World Economic Forum (WEF), and the International Institute for Management Development (IMD) also plays a crucial role. The results reveal that Thailand is far behind other countries. The number of users of broadband, and computers in general, is lower in Thailand than in other countries. Thais are mainly users, not technology developers. Also, the political situation in Thailand is not stable; the government changes too frequently, which means that policies change, too. The ICT law for digital money or cybersecurity has not been delivered, so neither users nor developers are secure. Although the number of internet users, such as those using social media, is growing, there is much abuse, including online bullying, intellectual property violations, and the infringement of privacy.

Presently, video games in Thailand are not for entertainment or playing for fun; they are esports for which players receive big rewards and great salaries. Thus, an increasing number of Thai gamers and teams are competing in national and international arenas. The Thai video game industry is growing and appears to have a bright future.

thatgamecompany

University of Southern California students Jenova Chen and Kellee Santiago founded the independent video game development company thatgamecompany on May 15, 2006. From the beginning, the company has been highly successful in developing several games with thitherto rather innovative elements in international game development; the games produced by thatgamecompany stand out because they attempt to provoke (positive) emotional responses from players. This means, among other things, that the games are characterized by a kind of specific flow in the gameplay that is considered lenient or relaxed by many players. To date, the company has produced and released *fIOW* (2007), *Flower* (2009), and *Journey* (2012). In 2012,

Kellee Santiago left the company. At the time of this writing, in 2019, thatgamecompany consisted of about thirty team members, and a new game, *Sky*, is being developed.

One of the company's characteristic approaches in developing a new game is that it sets out to first decide on the range of emotions the new game is intended to provoke. This, of course, differs substantially from the most popular approaches in the game development industry, where developers often approach a new game with reflections on game mechanics, genre details, or aesthetics. Both cofounders, Chen and Santiago, stressed in several interviews that the company wishes to design creative games that trigger emotional responses in the players, especially optimistic and positive feelings as opposed to excitement and fear, which, in the cofounders' eyes, are rather characteristic for popular games overall. With this, thatgamecompany has also set out to change the video game industry and provide intuitive and innovative games. It is a declared intent of the company not to produce blockbuster games with a big budget, as, according to Chen, financial pressure could stifle innovation.

The first game released by the company was a PlayStation 3 version of *fIOW*, which was based on an earlier game with the same name that had been developed by the cofounders and a team as part of student project. It became the most downloaded game on the PlayStation Network in 2007. After this, *Flower* equally claimed critical praise. The game won several awards, including Best Independent Game of 2009, at the Spike Video Game Awards. *Journey* (2012) continued the success story of the company and was even more successful than its

predecessors. The game's innovative use of music (instead of language) as a communication tool within gameplay was particularly praised by critics.

3-D Hardware

Video game consoles and personal computers use internal 3-D visual effects cards and external 3-D devices to create increased depth of field within game spaces. This entry focuses on the external forms of 3-D hardware that create stereoscopic 3-D images. The term *stereoscopic* comes from the word *stereopsis*, which refers to the visual effect that occurs when two corresponding images are simultaneously presented at strategic angles and decoded through special frames to create the illusion of z-axis depth.

The stereoscopic 3-D process makes images appear in front of or behind a screen, despite their projection or presentation on a screen. This process is possible because of the distance between the viewer's eyes. Each eye has a different perspective on the world. Differences between the two views work as depth cues for the brain, which automatically converts this information into a focused image. The eyes perform two essential tasks as part of this process. They focus

and converge on objects by turning at complementary angles. The stereoscopic 3-D process disrupts this activity by providing different depth cues for each eye. The brain compensates for this difference and brings the image into focus at an illusory point of convergence.

Stereoscopic 3-D hardware produces two corresponding images on a screen in different formats or presents separate images for each eye side by side. There are a number of ways that hardware for 3-D video games can combine the separate input images into one stereoscopic image. Tabletop games created by Coleco and Bandai created the stereoscopic effect by positioning a half-silvered mirror inside the hardware to superimpose one reflected video display over another transmitted video display. Both game consoles licensed SEGA's *Zaxxon* (1982) title to promote their 3-D hardware.

Another way to achieve the stereoscopic effect is to present the right and left images in an alternating sequence that is synced to the separate right and left eye shutters on the viewer's glasses. The earliest 3-D video game to appear in arcades was SEGA's *SubRoc-3D* (1982), and it used a shutter mechanism to achieve the stereoscopic effect. To experience the 3-D effect of *SubRoc-3D*, the user placed his or her face into a "periscope" eyepiece. The eyepiece partitioned the player's view and delivered individual images to each eye. Inside the eyepiece, a mechanism controlling two synchronized disks modified the flickering images on the screen to create a shutter-based 3-D illusion.

During the early part of the 1980s, shutter-based 3-D video game hardware began making its way to the home entertainment market. In 1983, the GCE/

Milton Bradley Vectrex video game system developed a peripheral device known as the Vectrex 3-D Imager. The 3-D illusion was created by an eyepiece similar to the *SubRoc-3D* “periscope.” The eyepiece plugged into the Vectrex system and synchronized a spinning disk inside the eyepiece to correspond with the images on the screen. In 1987, 3-D peripherals for home entertainment systems, including Nintendo’s 3D System Scope and Adaptor and SEGA’s 3D Glasses and later the SEGAScope 3-D, created a similar effect using liquid crystal lenses that were darkened and lightened to correspond with the alternating images on-screen, separating the images sent to the player’s eyes to create the stereoscopic effect.

Also in 1987, anaglyph 3-D hardware was used to create a stereoscopic 3-D effect by presenting images in two colors (usually red and cyan) that were decoded by glasses with corresponding colors. The anaglyph mode of 3-D was one of the most common types of 3-D hardware throughout the 1980s, 1990s, and 2000s. The only hardware required for this 3-D process is a pair of anaglyph 3-D glasses and a game that presents its images in an anaglyph form. Examples include *3-D Worldrunner* (1987), *Rad Racer* (1987), and *JJ* (1987), all produced by Square for the Nintendo Entertainment System (NES). Other anaglyph games include *Orb 3D* (1990), *Jim Power: The Lost Dimension in 3-D* (1993), *Magic Carpet* (1994), *Descent* (1995), *Duke Nukem 3D* (1996), *Sly 3: Honor among Thieves* (2005), *G-Force* (2009), *Toy Story Mania!* (2009), and *Skate 2* (2009). The anaglyph 3-D process never attained widespread popularity because the 3-D images are rarely sharp enough to sustain prolonged viewing.

In 1995, Nintendo developed a unique portable 3-D video game system, the Nintendo Virtual Boy. Advertised as “so advanced it can’t be viewed on conventional screens,” the Virtual Boy system displayed a monochromatic red 3-D image. The 3-D illusion was produced by separating the player’s eyes inside the eyepiece. Each eye was given its own view of a red LED screen regulated by oscillating mirrors. The movements of the mirrors were coordinated so that the two images could be used to create a 3-D illusion.

Since the turn of the twenty-first century, more sophisticated 3-D shutter glasses have been developed to work in tandem with emitters or software for video game consoles (most prominently the Nvidia 3D Vision technology). Typically, emitters sit on top of a 3-D television and sync the shutter speed of the dual-image presentation to the shutter speed of the two lenses on the glasses via radio waves or infrared signals. Alternatively, the software works in tandem with the glasses to regulate the opacity of the lenses. The lenses open and close at a shutter speed that corresponds to the alternating images on the screen, separating what each eye sees and creating the 3-D illusion. Games such as *Gran Turismo 5* (2010), *James Cameron’s Avatar: The Game* (2009), *Super Stardust HD* (2-D version, 2007; 3-D version, 2010), and *Wipeout* (2010) used this hardware.

Autostereoscopic 3-D technology makes glasses unnecessary through the inclusion of an additional screen in front of the screen known as a *parallax barrier*. The parallax barrier separates the image for the viewer and creates the 3-D effect without the assistance of 3-D glasses. The Nintendo 3DS (2011) made this autostereoscopic 3-D experience available to

mobile gamers. Popular games such as *Mario Kart 7* (2011), *Super Mario 3D Land* (2011), and *Pokémon Sun and Moon* (2016) take advantage of the 3-D capabilities with various levels of success. *Super Mario 3D Land* is particularly applauded for its ability to translate the beloved aspects of the franchise into a 3-D experience.

The lessons and innovations of 3-D hardware have paved the way for virtual reality (VR) technology. Although VR technology has struggled to penetrate the consumer market, a number of companies have produced VR headsets, including Oculus, PlayStation, Samsung, and HTC Vive, in the hopes that gamers will embrace immersive gameplay. Increasingly, these technologies enhance the effects of 3-D hardware by pairing the visual component with motion controllers and gesture-based game mechanics. While gesture-based gameplay has been available since the Nintendo U-Force (1989), the technology only achieved widespread adoption in the early 2000s thanks to the Nintendo Wii (2006), PlayStation Eye (2007), Microsoft Kinect (2010), and PlayStation Move (2010). PlayStation VR (2016) evolved from this earlier technology and features games such as *Rez Infinite* (2016), *Astro Bot Rescue Mission* (2018), and *Tetris Effect* (2018). In reviews, the game experience is often described as unique, disorienting, and transporting.

3DO Interactive Multiplayer

Trip Hawkins founded Electronic Arts (EA) in 1982. As the chairman of the most powerful entertainment software publisher at the beginning of the 1990s, he was well aware of the challenges faced by the video game industry. Hawkins sought to alleviate the development process and reduce confusion for prospective buyers. He proposed a new vision for the industry: the creation of a single technological standard that could be licensed to multiple manufacturers. At the same time, Hawkins wanted to create a cutting-edge multimedia system that could play games with three-dimensional graphics and video, along with educational software, movies, and music CDs. In 1992, Hawkins introduced this ambitious vision of convergence to the public: the 3DO Interactive Multiplayer (or 3DO) was being sketched, and a new company was founded to develop the project.

Along with Commodore's CDTV, the Philips CD-i, and the Fujitsu FM Towns Marty, the 3DO was one of the first

entertainment units to feature a built-in CD-ROM drive. When it launched in October 1993, it was the most powerful gaming system available. The console was based on a 32-bit RISC (reduced instruction set computing) processor running at 12.5 MHz, assisted by two video coprocessors running at 25 MHz. On top of the two megabytes of system RAM, another megabyte was dedicated to graphics, and its 2X drive could transfer up to 300 kilobytes of data per second. The system was able to display 24-bit color images (16 million colors) at a theoretical maximum resolution of 640-by-480 pixels (most games used the 320-by-240 standard). Thanks to the system's graphical processors, these images could be made transparent, warped, or applied as a texture on a three-dimensional surface. The 3DO was also proficient with full-motion video (FMV), and an extension, the Digital Video Module released in 1994, allowed the playback of movies on CDs.

In the early 1990s, Hawkins managed to create a lot of enthusiasm for the 3DO. Major manufacturers such as Matsushita/Panasonic, Goldstar, and AT&T were willing to invest in the venture, each planning to develop their own version of the system. Hawkins also convinced over fifty companies to sign developing agreements by loosening the restrictions and fees (\$3 licensing fee per game sold, vs. \$9 or \$12 for the competition). However, the suggested price of Panasonic's FZ-1 (\$699.95), the first 3DO to be manufactured, tainted this early confidence with doubt. Few consumers were willing to pay the price, and very few games were available upon release; Hawkins's venture was awarded "worst system launch" in *Electronic Gaming Monthly's* annual contest. In 1994, the console received the "best product of the

year" award from *Time* magazine. However, growing notoriety, the release of quality games, and a price cut down to \$399 were not enough to increase sales. As John Markoff of the *New York Times* observed, at the end of 1994, the 3DO was already facing a make-or-break season (Markoff 1994). Production of 3DO hardware and games stopped after 1996.

The console was at the forefront of the short-lived interactive movie craze. Many of the FMV games, such as *MegaRace* (1994), *Microcosm* (1994), *Night Trap* (1994), *D* (1995), and *The Daedalus Encounter* (1995), were technically superior on the 3DO. Several space shooting games were released throughout the system's three-year life span, either shooting galleries on rails that heavily relied on prerendered courses (such as *Star Wars: Rebel Assault* [1994] and *Novastorm* [1994]) or real three-dimensional games such as *Wing Commander III: Heart of the Tiger* (1994), *Total Eclipse* (1994), and the *Shockwave* series made exclusively for the console. Crystal Dynamic's *Gex* was proclaimed 3DO's mascot upon its Christmas 1994 release, but the title would later be ported to other systems.

In 1994, the sport simulation genre started a successful transition to three-dimensional graphics and TV-style presentation with EA's *John Madden's Football '93* and *FIFA International Soccer*. The console's most praised titles were racing games: the first in the *Need for Speed* (1994) series and a port of *Road Rash* (1994). Despite some truly impressive titles, the 3DO company's liberal licensing policy ended up diminishing the overall quality of the software library.

Time

Theories of time in video games can roughly be divided into two categories (Nitsche 2007, 145). Formalist time encompasses timers and timing mechanisms, the time it takes for game events to occur, and the passing of the player's

time. Experiential time takes into account the player's perception of the passing of time based on the formal properties of time in the game.

The role of countdown timers has changed in scope as games have evolved, but their purpose is largely the same. Time limits add additional pressure to actions by threat of terminating play (Wolf 2001, 88). Some timers are visually displayed on-screen. The timer in the upper right-hand corner of *Super Mario Bros.* (1985) quickly counted down to zero to hurry the player through the stage. Players of Activision's *Pitfall* (1982) had just 20 minutes to find the thirty-two treasures scattered around the jungle. Other timers tick away the seconds without visual display. Although it is never explicitly stated, each round of *Freeway* (1981) is limited to 136 seconds. Clocks can also measure performance—the "high score" is often the time it takes players to complete a level or race (Wolf 2001, 89).

Jesper Juul established a framework for the mapping of play time onto event time (Juul 2004, 131). Each game comprises a sequence of events that are supposed to have unfolded in some order as governed by an underlying logic (e.g., state changes, the simulation of processes, changes in the visual display, the passing of a narrative). These events do not need to be experienced in a set sequential order nor at the same rate. A *Quake* (1996) deathmatch unfolds with a direct mapping of play time to event time. In *SimCity* (1989), on the other hand, the passing of two minutes of play time might equal one year of event time in the simulation. Cutscenes in games suspend play time entirely in favor of event time. Pausing your party to select

an attack strategy in *Knights of the Old Republic* (2003) pauses event time while continuing play time.

The relationship between play time and event time can also involve other changes in the game state, such as resetting, loading, and saving. Dying during a single-player campaign of *Halo: Reach* (2010) resets the game state to a previously saved checkpoint, in which event time is rewound but play time continues. As a new area of Tokyo loads in *Persona 5* (2016), visual cues signal whether event time has been momentarily suspended or whether a larger passage of time has occurred. Game saves, according to Juul, are “manipulations of game time” that not only let a game be broken into multiple play sessions but also allow ways to roll back event time if players are unsatisfied with choices made during play time (Juul 2004, 138). Some genres, such as rogue-like games, eschew saving player progress in favor of a game experience in which the same event time is repeated.

These formal properties are useful for understanding the structure of time, but they do not describe how a player experiences time. This perspective “tries to describe a player’s comprehension of temporal situations in games” (Nitsche 2007, 146). Continuing play after death, for example, can pose different interpretations based on how the game state is altered. If players restart from a checkpoint, they might resume with a snapshot of the game that was taken at the point progress was saved. They would have lost their progress and therefore be resuming with the same health, equipment, or statistics. Some games save this kind of statistical progress, treating the player’s time as external to the event time of the game. For example, in *Bloodborne* (2015),

players may return to the hub location to heal and upgrade their character, but defeated enemies will repopulate its world.

Some games persist even after the player has turned them off. Massively multiplayer online (MMO) games are set in worlds that continue on the server for other players. MMOs blend this continuous time with instanced events—dungeons that are created at the player’s request and can exist simultaneously with other instances of the same space. Other games, such as *Animal Crossing: New Leaf* (2012), use the Nintendo 3DS system clock to judge how much time has passed since the game was last played and resume as if the game world had continued in real time while the system was off. In *Animal Crossing*, certain events occur only on specified days of the week, in-game holidays are marked on a real calendar, and events in the world have a day-and-night cycle. Additionally, if the player does not turn on the game for a few days, weeds will have sprouted around the town, and relationships with the other townsfolk may suffer from inattentiveness.

Michael Nitsche and Craig Lindley advocate for the essentiality of space in the understanding of time in video games. A player’s movement through space maps to a temporal shift that involves play time, event time, and experiential time. The clock ticks away as a player moves forward through a level toward an objective, but it continues to tick if the player gets sidetracked and decides to explore an empty house along the side of the road. Because many games want to give players the freedom to proceed to a destination at different rates, many events in games are triggered only

once a location is reached. Tasked with hurrying to the next location, players might spend twenty minutes getting somewhere that should only take five. Unless programmed to keep track of this time, the game state is indifferent to the play time—the woman giving you your next mission makes no mention of your tardiness.

Understanding the space of a game can have a temporal impact. According to its creator, balancing the popular *Counter-Strike* (1999) map “de_Dust” involved the careful timing of where the two sides would meet at the beginning of a round (Nitsche 2007, 147). A game world that does not allow players to teleport or fast travel across an expansive map may feel larger than one that does because all the space in between two locations must be experienced as play time. The same is true for games with distinct levels that take place in different locations. Although no play time has passed, J. C. Denton in *Deus Ex* (2000) is assumed to have experienced diegetic progress in game time when traveling from New York City to Hong Kong.

Time in video games results from the negotiation of the formal properties of passing time and changing game states as encoded into the game and the player’s experience of the time spent playing.

Tool-Assisted Superplay (TAS)

On November 2003, moSMB3.wmv—an early viral video—circulated on the internet; it appeared to display superhuman performance in *Super Mario Bros. 3* (1988). The creator, Morimoto, not only finished the game in record-breaking time but also toyed with enemies and showed off seemingly impossible skills. However, the video was not the result of a human playing in real time but the outcome of meticulous planning and programming—a tool-assisted superplay (TAS). Morimoto’s detailed explanations were originally only available in Japanese; therefore, after discovering the circumstances, some English-speaking viewers felt cheated, but others were excited by the newfound possibilities. Among them was Joel “Bisqwit” Yliluoma, who founded Tasvideos.org, which is still functioning as the archive, forum, and database for the TAS community today (LeMieux 2014).

The basis for any TAS is a controller input file, which is created from a linear sequence of commands. Those files can be played back in emulators to recreate and optimize recorded runs. By using this technique, TAS creators can explore the limits of gameplay. Some seek to tweak certain aspects or to display perfection or almost godlike skill; others focus more on aesthetic and entertaining representation. Similar to classic speedruns, different categories or extra goals are available for the creation of TAS videos, for instance, in pacifist runs. Another similarity to speedruns lies in the importance of preparation and routing, especially the knowledge of game mechanics, useful glitches, and common tricks. In addition to these theoretical requirements, TAS creators can take advantage of a vast arsenal of tools. Using emulators enables pausing or speeding up games as well as editing inputs at frame-specific accuracy or rewinding actions via savestates. Additionally, reading out data from RAM and accessing random number generators open more possibilities, such as manipulating drop rates and other hidden variables. Some creators even utilize code mining to inspect the underlying algorithms or the usage of scripting language for the automation of certain in-game tasks.

James Newman describes *superplay* as more than “beating” the game but as practices “bound together by a common desire to demonstrate mastery of the game through performance” (2008, 123). This notion can be retraced in modern TAS videos that deviate from the pursuit of pure speed and perfection to create innovative and creative forms of

superplay. For example, Julian “Masterjun” N. demonstrated in 2012 that some glitches allow creators to execute arbitrary code through manipulation of the instruction pointer. This method was used to force games to skip directly to the ending or to alter the game mechanics in various fundamental ways.

Another example is TASBot, which consists of a Nintendo R.O.B. holding a circuit board and is able to play TAS files on original console-based hardware. It was created in December 2013 by Allan “dwangoAC” Cecil and became popular after debuting its console-verification skills on *Awesome Games Done Quick* 2014. Cecil emphasizes that this endeavor has entertaining as well as educational elements, especially considering its similarities to hacking. In 2016, TASBot and game-breaking glitches came together in presenting *Pokémon Plays Twitch*. In this demonstration, arbitrary code execution was used to take over an original *Pokémon* (1996) cartridge inside a Super Game Boy inside a Super Nintendo Entertainment System (SNES). Afterward, raw IRC data was cleaned, translated, and sent through the controller cords to be displayed live on the stage and via Twitch (Orland 2015), proving that years after the original moSMB3.wmv, tool-assisted human-machine interaction can still surprise and excite people.

Touchscreen Games

Touchscreen games use computer interfaces that afford direct interaction with the screen, whether by touch of the hand or finger or through the use of an object, such as stylus. Contact with the screen generally signals—and signifies—a “touch,” resulting in a diegetic action or core mechanic within a game. While touchscreen games have existed throughout much of video

game history, they have proliferated in the last decade and, to some degree, coalesced under the term *casual games*, thanks to the introduction of smartphones and tablets built around touchscreens. Touch controls are often considered intuitive and easy to use and are often referred to as *gestural*, *mimetic*, or *natural* user interfaces for their appropriation of preconditioned everyday hand gestures for interaction (such as tapping, dragging, swiping, pinching, and tracing). Video games, however, present a diverse array of touchscreen methods and gameplay mechanics.

TOUCH AND TECHNOLOGY: A BRIEF HISTORY

Touch has long served conceptually as a holy grail of presence or intimacy for various interactive and tele-technologies (“Reach out and touch someone,” as AT&T urged telephone users to do metaphorically). Modern touchscreens augment the rather “flat” experience of touching glass displays with other haptic feedback cues (such as visuals, sounds, vibrations, and force feedback) to imbue touch with synesthetic enhancements. However, historians note that touchscreen development diverged from other haptic technologies and has its own path of development (see Parisi 2018). This history begins with antecedents to the modern-day touchscreen stylus—notably, developments in pen computing in the 1950s, including a light pen for MIT’s influential Whirlwind computer and the relatively unknown Stylator tablet (1957). Ivan Sutherland’s *Sketchpad* (1963) and Alan Kay’s Dynabook concept for personal computing (1968) would later popularize the idea of direct screen

Some touchscreen games in the arcade of LaserTag Adventure in Waukesha, Wisconsin. (Courtesy of Mark J. P. Wolf)

contact via pen or stylus among computer engineers, techno-futurists, and science fiction enthusiasts (e.g., Lieutenant Uhura's stylus-enabled electronic clipboard on *Star Trek* [1966–68]).

Later breakthroughs demonstrated that touchscreens could also respond to the human hand. Eric A. Johnson, an engineer at the Royal Radar Establishment in Malvern, England, invented a desktop screen in 1965 that could sense single-finger touch using a capacitive conductor. Capacitive touchscreens have a thin coating of conductive material that responds to a disturbance in its electromagnetic field—such as the conductivity of a finger touch. Although capacitive touchscreens would eventually become the dominant touch technology, the first broadly available touchscreens

used resistive, or pressure-sensitive, detection. Cheaper and more durable than capacitive touch, resistive touchscreens initially made their way into some commercial (such as ATMs) and industrial applications. These touchscreens were limited to a single point of contact, but multitouch displays were already emerging in the lab: engineer Nimish Mehta's multitouch Flexible Machine Interface at the University of Toronto in 1982 was followed in rapid succession by a multitouch screen at Bell Labs in 1984 and the first multiscreen tablet in 1985, again at the University of Toronto. Such lab-based advances in the 1980s and 1990s would not become widely commercialized until the emergence of smartphones and tablets in the early 2000s.

EARLY TOUCHSCREENS AND THEIR GAMES

A number of early media technologies invited playful touching of screens and displays, even if the feedback was very limited or even imaginary. Early encounters by users with touch-responsive personal computers included the PLATO IV (1972), a computer-assisted instruction system introduced at the University of Illinois, and the Hewlett-Packard HP-150 (1983), which is considered the first commercially released touchscreen PC. Both PCs relied on infrared sensors mounted in the display frame to detect contact. However, most of the elements constituting contemporary touchscreen gaming began to fall into place starting in the 1990s. The Apple Newton MessagePad (1993) was the first touchscreen-based personal digital assistant (or PDA, as coined by Apple), which offered games such as *Backgammon*, *Checkers*, and *Risk* (1957) as well as some simple action games, including a variant of the early computer classic “snake” game (in which an obstructing “tail” grows behind the player). Newton also supported a dedicated porting community, and a number of Infocom text-adventure games, such as *Zork I* (1980), became available on Newton, with players using the stylus to tap the screen or handwrite actions. Though much maligned, the Newton established the form factor and interface that would inform the next evolution in PDAs: the PalmPilot.

The PalmPilot’s grayscale screen and stylus operation supported some surprisingly detailed and involving video games, including board games, card games, pinball simulators, side-scrolling platformers such as *Shadow Thief* (1998), and a

slew of role-playing games (RPGs) likely informed by the popularity of *The Legend of Zelda: Link’s Awakening* (1993) on Nintendo’s Game Boy handheld system. In 1999, Gamasutra called PalmPilot a “Game Boy for grown-ups,” as the prevalence of RPGs on PalmPilots, such as *Dragon Bane* (1998), *Kyle’s Quest* (1998), and *Ackeron: Dark Sun* (2000), attest. But the most distributed PalmPilot game was the device-bundled title *Giraffe* (1997), a *Space Invaders*-style game that taught users Palm’s particular graphical “language” (called Graffiti) for accurate handwriting recognition.

TOUCHSCREENS AND DEDICATED GAMING DEVICES

The 1990s also introduced the first touchscreen for a game-centric handheld device: Tiger Electronics’ Game.com (1997) and Game.com Pocket Pro (1999). Both devices were effectively dead on arrival due to their outdated form factors and slow display refresh rates (known as *ghosting*). Despite this false start, handheld touchscreen gaming would flourish under Nintendo’s direction. Facing stiff competition from consoles and other devices in the early 2000s, Nintendo rolled out the DS (Dual Screen) handheld in 2004, a clamshell that included a stylus and resistive touch on the lower of its two full-color screens. Introduced under the advertising banner “Touching is good,” the DS supported a slew of stylus-based touchscreen games, including caring for a pet in *Nintendogs* (2005); helping with meal preparation in *Cooking Mama* (2006); solving puzzles in the best-selling *Brain Age: Train Your Brain in Minutes a Day!* (2006); wielding the stylus like a scalpel in *Trauma Center: Under the Knife*

(2005); navigating avatars through adventures or challenging environments in *The Legend of Zelda: Phantom Hourglass* (2007) and *Kirby's Canvas Curse* (2005); and aiming and shooting in action games such as *Metroid Prime Hunters* (2006). Nintendo even released a pair of drumstick-like styluses for the drumming rhythm game *Taiko no Tatsujin* (2007). Touchscreens were so successful for Nintendo that the DS would become the second-best-selling game device of all time (just behind Sony PlayStation 2). Nintendo continued to tweak the DS line, but its most notable change came with the addition of an autostereographic 3-D screen on the 3DS (2011). However, touch capability remained relatively consistent, even as the limits of resistive stylus-oriented touchscreen use were tested in games such as *Kid Icarus: Uprising* (2012), a third-person shooter released for the 3DS.

The only major competitor to the DS line was the Sony PlayStation Portable (PSP, 2004) and its successor, the Vita (2012). Sony did not introduce a touchscreen until the Vita, which has a touchscreen on the front and touchpad on the back. The platformer game *Tearaway* (2013) makes notable use of the double-sided touch capability, as players touching the back can create the impression of their fingers intruding into the game world from below. *Touch My Katamari* (2012), a Vita-only installment in the popular series, also uses the back touch panel to stretch or shrink the Katamari ball, while fingers on the touchscreen navigate. Such novel applications aside, the market for dedicated gaming handhelds has been eroded by smartphones and tablets, and Sony ended Vita production in 2019.

Nintendo's response to dwindling market share blurs the divide between handheld and console gaming, unveiling in recent years touchscreen devices that operate as both. The Wii U (2012) features a resistive touchscreen "digitizer" and stylus built into its GamePad, which serves as a touchable handheld display in both off-TV and connected use. Various *Mario* and *Zelda* games reigned as the best-selling titles for Wii U, and the device may be best known for its successful touch-enabled remakes of *The Legend of Zelda* classics *The Wind Waker HD* (2013) and *Twilight Princess HD* (2016). In both games, map wayfinding and handling inventory management are touch enabled to streamline nonessential gameplay. Perhaps the most innovative implementation of the Wii U's touchscreen is *Super Mario Maker* (2015), which allows players to make their own game levels by touching and arranging beams, blocks, and other game objects.

The Nintendo Switch (2017) platform continues in the same vein but offers detachable Joy-Con controllers on the sides of the screen for more flexibility. The Switch also marks Nintendo's first foray into capacitive, multitouch screen technology that jettisons the stylus and brings the device's touch capabilities more in line with those found on smartphones and tablets. A notable touch game for the Switch is *Sushi Striker: The Way of Sushidos* (2018), a challenging action puzzler that requires players to tap and drag plates of sushi to collect them and then throw them at an opponent. Many players report the game's hectic action is better suited to the Switch's touchscreen than its Joy-Con controllers. Thus far, however, relatively few new Switch games rely on its

touchscreen, and most of those are updates of Wii U games (such as the platformer *Rayman Legends Definitive Edition* [2017]) or ports from the most successful touchscreen devices of the past decade: smartphones and tablets.

SMARTPHONE AND TABLET TOUCHSCREEN GAMING

Although Apple did not invent multi-touch, the iPhone, in 2007, and iPad, in 2010, successfully inaugurated a sustainable market for smartphone and tablet touchscreens (and, later, touchscreen watches) that is now dominated by Apple and Google and their respective download stores for apps and games. Perhaps the first contemporary smartphone game is *Lights Out* (2007), a puzzle game that has players touching the screen to turn off patterns of lights. *Lights Out* is a remake of the 1995 *Lights Out* handheld game that featured illuminating buttons, which in turn is a remake of a game found on *Merlin* (1978), an early handheld device that used a touchable LED display membrane (and was the best-selling handheld game of 1980). Another early and popular touchscreen title is *Paper Toss* (2009), which introduced many players to the playful potential of swiping or flicking a finger across the surface of the screen to throw an object. But the *Citizen Kane* of touchscreen gaming is arguably Rovio Entertainment's *Angry Birds* (2009 for iOS; 2010 for Android). *Angry Birds* offers a simple touch-and-drag mechanic to aim and stretch a slingshot to launch birds at a variety of building block structures housing sarcastically chortling pigs. *Angry Birds* successfully distills casual gaming's serial interruptible format and

paves the way for the “everyday ubiquity” (see Steirer and Barnes 2019) of touchscreen gaming in every aspect of daily life. This includes using the connectivity and telepresence of smartphones to create playful interactions with faraway opponents, as seen in *Words with Friends* (2009), an adaptation of *Scrabble* (1938), and *Draw Something* (2012), inspired by *Pictionary* (1985).

Although touchscreen interfaces have become synonymous with casual gaming, today, we find every genre and type of play experience on touchscreens. One unique form not found on PCs or consoles is location-driven augmented reality (AR) gaming, which uses GPS tracking and embedded cameras in mobile devices to blend physical and virtual spaces into touchable play. The company Niantic pioneered the genre with *Ingress* (2012) and built on that game's collected location data (such as landmarks, statues, and parks) to develop *Pokémon Go* (2016). The hit game compelled players to leave the house to catch Pokémon in the “wild,” visit PokéStops for collectible items, and control Pokémon Gyms with networked teams of other players.

While AR touchscreen games incorporate physical spaces and material objects, game artists are restoring the physicality of other humans. The dancing game *Bounden* (2014) presents a mix of Twister (1966) and ballet; two players mutually hold a touchscreen while their bodies move and touch as guided by on-screen markers. Similarly, UCLA Game Lab artist Nick Crockett's *Super Tap-Out Saga* (2014) is a boxing game that encourages two players to physically push, pull, and block each other while attempting to tap on their opponent's on-screen avatar.

The success of touchscreen gaming has also been buoyed by—and highly criticized for—capitalizing on a free-to-play (F2P), or “freemium,” economic model that uses financial microtransactions during gameplay for upgrades, features, and boosts. The match-three puzzle game *Candy Crush Saga* (2012), considered the most financially successful touchscreen game to date, uses in-game payments to buy extra lives, moves, or levels and includes a social economics dimension as well, as players can share lives with friends through Facebook. Peak Games, the developer of the minigame titles *Toy Blast* (2015) and *Toon Blast* (2017), pairs the freemium model with aggressive advertising to cut through the clutter of free downloadable games. For example, actor Ryan Reynolds appears in humorous ads about playing *Toon Blast* as a tie-in to *Deadpool 2*, and game company Supercell relies on extensive television ad buys (including a spot in Super Bowl XLIX) to drive downloads of its popular series of strategy games, including *Clash of Clans* (2012), *Boom Beach* (2014), and *Clash Royale* (2016).

ARCADE GAME TOUCHSCREENS

Arcade games have long used haptic feedback to enhance immersion, but touching screens—either directly or with an intermediary object—has been relatively limited, as most arcade cabinets prize smudge-free displays and the precision interaction afforded by hardware controllers. One notable exception is gambling machines, such as touchscreen slots and various card games of chance, which can be found in many casinos and bars in seemingly endless iterations. One

high-fidelity entry in this category is *Big Tony's PokerKard* (2008), a Texas Hold'em poker game that uses a touchscreen on an arcade-like cocktail cabinet to emulate a poker table.

Arcades in Japan and South Korea have expanded notions of touchable play surfaces and screens. One interesting genre is digital collectible card games, in which players arrange card decks on a touchable, position-sensitive surface, with the results displayed above on a conventional screen; *World Club Champion Football* (2002) and the wargame *Sangokushi Taisen* (2005) are popular examples. Perhaps unsurprisingly, rhythm-and-dance games are popular touchscreen titles, and SEGA's “performi” line of games features the stand-out title *Chunithm* (2014). Combining a glowing touchscreen-like piano keyboard with motion controls, the game requires players to hammer on the keys as well as lift their hands in sync with a flowing timeline, resulting in a hyperstylized pantomime of a concert pianist. While *Chunithm* is a Japan-only title, Pentavision Entertainment's *DJMax Technika* (2008), developed and released in South Korea, has gone international, and the music-mixing game has players rapidly tapping notes on a multitouch screen to prevent a break in a song's playback.

Outside of Asia, more conventional arcades present upscaled adaptations of touchable smartphone and tablet games. Slashing flying watermelons in the arcade version of *Fruit Ninja FX 2* (2010) involves more of the arm and shoulder, while *Bejeweled* (2011) for the arcade can accommodate up to four players and be outfitted with a ticket redemption feature. A more innovative use of touchscreen mechanics is found in *Black Out*

(2012), which uses a *Paper Toss*-like flick to launch impish characters called Goo-gabongas at a giant sun to blot it out with their splatting bodies. As *Black Out*'s retro cabinet and prize-dispensing compartment suggest, arcades and amusement parks are taking cues from historical midway and carnival games to create modern hybrids of touchscreens and physical props. *Ice Man* (2017) evokes water cannon-styled games, allowing two players to shoot virtual zombies with actual water and freeze them on-screen as real mist rises from the bottom of the cabinet to enhance the atmosphere. A similarly engineered machine, *Go Ball-Istic* (2010), reworks the classic ball toss game, allowing players to hit various targets on a screen by throwing soft playballs at it.

FUTURE OF TOUCH: BEYOND THE SCREEN

As arcade adaptations suggest, touchscreens have saturated our culture and crossed over into almost every space and setting. Touchscreen use is now showing signs of maturation and retrenchment after early excesses (such as touchscreen-dominant automobile dashboard displays) and failed experiments. Apple, for example, has abandoned its "3D Touch" feature, introduced on the iPhone 6 line in 2015, which included pressure-sensitive touch for another layer of gesture and interface. However, for designers, artists, and technologists, touching screens and projections remains an opportunity for invention. For example, at Two Bit Circus, a "micro amusement park" in Los Angeles (its CEO is Brent Bushnell, son of Atari cofounder Nolan Bushnell), players in carnival-like booths

destroy screen-projected buildings by swinging a small-scale wrecking ball or throw colorful balls at virtual balloons to pop them. The future of touch is also moving beyond the boundary of the wall or screen to complement the more immersive environments promised by augmented, virtual, and mixed reality. If touchscreens today place video games firmly, if flatly, within our hands, immersive environments that allow us to reach out and touch something—or someone—hover just at the edge of our grasp.

Treasure Co. Ltd.

Treasure Co. Ltd. is a small Japanese video game developer primarily known for its innovative action titles and unusually high-quality licensed games. Treasure’s games (excepting licensed titles) typically feature a high degree of difficulty, large-scale boss fights, technical aptitude (particularly *Sin & Punishment* [2000] for the Nintendo 64), and an odd sense of humor. These features have garnered the company a dedicated following.

The company was founded on June 19, 1992, by Masato Maegawa, a former programmer at Konami. Although reasons for Maegawa’s departure are unclear, it is commonly believed to have been motivated by a desire for greater creative freedom. This led to a pervasive, although now provably false, rumor that Treasure had an internal policy forbidding the development of sequels.

Creativity is a key theme in Treasure’s games and in its development practices.

Most of its major successes involve innovations in established genres. Its first and possibly best-known title, *Gunstar Heroes* (1993) for the SEGA Genesis, takes the classic run-and-gun platform genre and adds several twists to the formula along with a sense of ironic humor. *Mischief Makers* (1997), for the Nintendo 64, is a platform game in which the core mechanic involves grabbing objects, characters, and enemies to shake them. The more recent arcade hit *Ikaruga* (2001) blends the classic scrolling shooter genre established by *Space Invaders* (1978) and *Galaxian* (1979) with a color-matching puzzle game.

In terms of its development process, Treasure’s games are developed by small teams, usually ranging from three to ten members. Team members are given a high degree of creative freedom. In a 2010 interview with Nintendo president Satoru Iwata, Maegawa (who at the time of the interview was president of Treasure) said, “Even today it’s normal for three people to be a team at our company. That way they can do what they want and really make it stand out.” Throughout the interview, Maegawa emphasized that Treasure employees are given creative freedom, leading to the unique nature of their games. In earlier interviews with gaming and media news website IGN (2005) and gaming news website lup.com (2007), Maegawa further emphasized that the teams decide what they want to design and the platform they are designing for. From the lup interview, he said, “Treasure supported N64 (Nintendo 64) because the team wanted to work on the system. I always listen to the team and they basically chose the N64 because they thought it would be easiest for them to create

games on. That was the same reason we decided to work on the Xbox 360.” Although Treasure’s first seven games all appeared on SEGA hardware, the company has since diversified, creating titles for a wide range of platforms from SEGA, Nintendo, Sony, and Microsoft.

As of 2018, Treasure is still active, having released *Gaist Crusher God* in 2014 for the Nintendo DS. In addition to full retail titles, the company has taken to digital distribution to rerelease its older titles via the Nintendo Wii Virtual Console and the Microsoft Xbox 360 Live Arcade.

Turkey

The Turkish game design and development scene is young and small compared to Western industry, but it is a rapidly growing market. Cetin Tucker, Erdal

Yilmaz, and Kursat Cagiltay (2015) discuss Turkish game development history in three levels. The first level is the “Beginner Level,” and it covers the 1980s. Personal computers were too expensive for Turkish people, so most of them could not afford to own a device to develop any game software. Some programmers developed simple tic-tac-toe-like games on mainframe computers at universities. Starting from mid-1980s, more affordable systems became available from Commodore, Sinclair, and Amstrad, and by the end of the 1980s, Amiga 500 systems became popular. A society of young gamers gathered around these popular systems, using computer magazines and a few programming books that published simple game code examples. At the end of this era, the first attempts at video game development, by a few indie groups, started to emerge. However, none succeeded in selling more than a thousand copies. The best-known Turkish game maker of this era is likely Mevlüt Dinç, a young game developer living in the United Kingdom, who developed world-famous titles for prominent game producers of the time. Some of these were Firebird Software’s *Gerry the Germ Goes Body Poppin’* (1985), System 3 Software’s *Last Ninja 2: Back with a Vengeance* (1988), and Activision’s *Hammerfist* (1990).

The next level, the “Amateur Level,” covers the 1990s (Tucker et al. 2015, 566). With the help of the Amiga 500, which had better multimedia capabilities, a few indie groups managed to publish the first examples of boxed games. The first title was Digital Dreams’ *The Dagger* (1992), a game inspired by the history of the Ottoman Empire. This was the first Turkish hit, selling twenty-two hundred copies in

Video games on display in a game store in Eskisehir, Turkey, on August 11, 2017. (Ipek Morel Diplikaya/Dreamstime.com)

two years. During this era, some other outstanding titles also managed to pass the one thousand-copy threshold, including Siliconworx's *Fields of Hope* (1993), which sold one thousand copies, and *Legends of İstanbul: Tulip Warriors* (1994), which sold two thousand copies. During the second half of the 1990s, as PCs became more affordable and penetrated into market, more titles were published by more financially powerful companies, such as Cartoon Studios' *Detective Storm* (1996) and a 1996 PC remake of *Legends of İstanbul*, which, bundled with computer magazines, had forty-five thousand copies distributed. The game that probably received the largest investment during this era was SEBIT Education and Information Technologies' *Piri the Explorer Ship* (1997).

The last level, the “Professional Level,” covers the first decade of the 2000s (Tucker et al. 2015, 566). At the beginning

of 2000s, Mevlüt Dinç moved from the United Kingdom to Turkey and launched Dinç Interactive (later Sobee Studios), which released many titles, including *Football Manager* (2003); *Magic Billiards with Semih Saygıner* (2004); *Istanbul Apocalypse Time* (2006), which was Turkey's first massively multiplayer online role-playing game (MMORPG); *Nightmare 22* (2006); *I Can Football* (2009); and *Supercan* (2011). These titles reached five hundred thousand to two million users. During this period, other young developers also started to publish their own titles. These include *The Ambush: Awakening* (2005, by 3TE Games), *Culpa Innata* (2007, by Momentum DTM), *Sovereign Symphony* (2007, by Ceidot Studios), and *Monochroma* (2014, by Nowhere Studios). Probably the most important series of this era was Taleworlds' *Mount and Blade* series, which began in 2008 and as of 2019 was still an

active and successful franchise in the world game market.

As smartphones started to take over the game market in Turkey, most young and small development groups started to develop games for them, as such games required less investment of time and money. Successful examples include Duello Games' *iSlash* (2010), Mild Mania's *Rop* (2015, iOS version), and Yunus Ayyıldız's *Hocus* (2015, iOS version). Some of these small groups and personal entrepreneurs eventually became start-ups, while other, larger game producers also produced globally popular titles in the mobile gaming scene, such as Gram Games' *1010!* (2017) and Peak Games' *Toy Blast* (2015).

Another title from this era worth mentioning because of its artistic interpretation is *Recontact Istanbul* (2015), by Eray Dinç and Simay Dinç, along with its sequel, *Recontact Istanbul 2: Eyes of Sky* (2017). Video artist Eray Dinç brought a brand-new interpretation of mobile gaming, defining a new art form, by creating a cinematographic detective simulation that criticizes the normalization of the phenomenon of "being watched" with the help of security cameras. *Recontact Istanbul* won the Best App Award at the Los Angeles New Media Film Festival in 2017.

VIDEO GAME DESIGN AND DEVELOPMENT EDUCATION

Small, private institutions offer short-term courses that teach necessary development skills in several programming languages that are popular in the gaming industry and courses to improve software-using skills in the areas of game engines, modeling and animation, and

the creation of game assets. Unfortunately, these institutions are presently only in big cities, where game development companies are established.

More promising progress can be found in universities. As of 2019, four universities, Bilgi University, Beykoz University, and Bahçeşehir University (BAU) in İstanbul and Eastern Mediterranean University in Northern Cyprus, offer bachelor's degrees in video game design. BAU also offers a video game design master's degree. Additionally, İstanbul Technical University's Game and Interaction Technologies Program, Middle East Technical University's Game Technologies Program, Hacettepe University's Computer Animation and Game Technologies Program, and İzmir Economy University's Video Game Technologies Program are the graduate-level programs offered by those universities. Among these, BAU puts an emphasis on the production and business development phases of the game design process, whereas others put an emphasis on the engineering and development process. The same universities have incubation centers for game start-ups and technopolis organizations that house some of Turkey's largest game production companies, an indicator that the Turkish game scene is now advancing to a more institutional level (which we could call the "Institutional Development Level"), that will hopefully, in the future, create a more rooted game development industry.

VR/AR LABORATORIES ESTABLISHED IN UNIVERSITIES

In January 2016, two universities announced the establishment of virtual

reality/augmented reality (VR/AR) research centers. The Giresun University Augmented Reality Research Center, for scientific research and development, is funded by university resources (Artırılmış Gerçeklik 2016). The other center is VR First BAU, in İstanbul (VR First 2016). BAU and Crytek joined forces to start Turkey's first VR laboratory at the Galata campus of the university, under the VR First Program, which is a global VR educational initiative to get students familiar with VR technologies. VR First BAU was also the first VR laboratory of the program (Sinclair 2016). In September 2016, VR First opened the second VR/AR laboratory in Turkey at the Middle East Technical University in Ankara, where the first game development incubation center, ATOM (Animation Technologies and Game Development Center), was also established in 2008 (ODTU Teknokent 2016). After only one year, in the beginning of 2017, VR First and Crytek split (Sinclair 2017), and VR First became independent, with the help of other partners, to achieve its goal: democratization of VR/AR innovation. Hacettepe University is the third university in Turkey to join the VR First network.

As of February 2019, VR First has a network of fifty-two VR/AR laboratories that connect several academic institutions all around the world (VR First 2019). The last VR/AR laboratory is the KARMA Lab of Koç University, which was established with the support of the İstanbul Development Agency. The aim of the laboratory is to support the development of new generation interfaces, including IOT systems, biosensors, and VR/AR technologies (Karma 2019).

ASSOCIATIONS

As of 2019, there are two game developer associations established in Turkey: the Game Developers Association of Turkey (TOGED), located in Ankara, and the Game Designers, Developers, and Publishers Association (OYUNDER), located in İstanbul. Although both associations have almost similar missions, such as the development of the domestic game ecosystem, the creation of a network for game professionals, and increased public awareness, according to members' profiles, TOGED is more business oriented, and OYUNDER is more focused on the individuals and employees (designers, developers, artists, lawyers, academicians, etc.) working in the sector, although some members are game development companies.

PRACTICES OF THE VIDEO GAME MARKET, MANAGEMENT, AND ECONOMY

There are roughly twenty-nine million gamers in Turkey, according to a 2016 report (Turkish Game Market 2016 Report – Gaming In Turkey 2016). Mobile gaming is very common, with more than twenty-two million gamers using mobile devices to play games. According to a 2017 survey conducted by OYUNDER among the members of the association, video game developers in Turkey are predominantly young (the average age is twenty-six) and male (92%), and they mostly work in small teams; 86.6 percent of game development teams have fewer than ten people. Most of these developers reported that they have never conducted any marketing research

(Şengün 2018). Şengün (2018) points out that Turkish game developers still have “indie characteristics of small groups, low funding, and under-emphasis on traditional marketing channels” (356).

As TOGED president Ali Erkin reports in one his interviews, in 2018, total video game exports of the member companies of TOGED were \$1.05 billion, an increase of more than 20 percent every year over the last four years (\$400 million in 2015; \$500 million in 2016; and \$700 million in 2017). Most of this income is from the export of mobile games, PC games, and serious games (including simulation systems), respectively. He adds that this number is slightly higher if exports of companies that are not TOGED members are also counted. Turkey’s video game industry is bright, with video game exports for 2023 projected to be more than \$2.5 billion dollars (Merlin’in Kazanı 2019).

Twin Galaxies

Twin Galaxies is the officially recognized worldwide authority on all video game scores and world records. The organization tracks player rankings and gaming statistics and regulates gaming contests and championship tournaments, with information dating from the 1930s and video game statistics from the early 1970s. As the electronic gaming industry’s

premier statistician, Twin Galaxies preserves the history of gaming in its database, which documents the historical milestones of the electronic gaming hobby as it evolves into a professional sport.

Founded in 1981, Twin Galaxies grew from modest origins as a video arcade to gain recognition as the official scorekeeper for the world of video game & pinball playing, vested with the authority to verify “official” world record high scores and crown new world champions. The Twin Galaxies Scoreboard was the creation of Walter Day, Twin Galaxies’ founder, who, on June 6, 1981, embarked on a series of business trips that took him through fifteen U.S. states in four months. Although his role as a traveling salesman was the focus of his trip, Day’s real passion was to visit as many video game arcades as possible and record the high scores he found on each game. Ten thousand miles and one hundred arcades later, on November 10, 1981, Day opened his own arcade in the sleepy Midwestern town of Ottumwa, Iowa. He named his arcade Twin Galaxies, a name that simply sprang out of his head one day. The name rolled off the tongue so easily and felt so familiar to Day that he actually thought he must have heard it being used somewhere as another company’s name. Not so—it was simply an inspirational thought, and the name has stood ever since.

On February 9, 1982, Twin Galaxies’ tranquil existence was altered when Day’s growing database of high score statistics was made available to the public as the Twin Galaxies National Scoreboard. In the coming years, the Twin Galaxies arcade, and the town of Ottumwa in general, was considered to be the number one hot spot for competitive video gaming, as

many significant tournaments and world record gaming attempts were performed there. As the organizational center of competitive video game playing, Twin Galaxies received immediate recognition from the major game manufacturers of the day—Atari, Midway, Williams Electronics, Universal, Stern, Nintendo, and Exidy—in addition to support from *RePlay* magazine and *Play Meter* magazine, the two premier coin-op publications of that era.

Twin Galaxies’ role as the scorekeeper grew in importance as “player rankings” became a major focus of the media. As the pioneer in ranking the top players, Twin Galaxies was called on to bring the superstar players together for many well-publicized contests and media events. For example, on November 7, 1982, *LIFE* magazine visited Twin Galaxies to capture sixteen of North America’s best players in a group photograph. On November 30, 1982, the mayor of Ottumwa, Jerry Parker, declared the hometown of Twin Galaxies to be the Video Game Capital of the World. That month, Ottumwa hosted the first North American Video Olympics, and two months later, on January 9, 1983, ABC-TV’s *That’s Incredible* came to Ottumwa, Iowa, to film nineteen of the world’s best players competing in the first-ever video game world championship. On March 19, 1983, players from around North America came to Twin Galaxies to join representatives of Atari, the Amusement Game Manufacturers Association (AGMA), *RePlay* magazine, and *Video Games* magazine as Iowa governor Terry Branstad acknowledged Twin Galaxies’ role as the official scorekeeper and crowning Ottumwa, Iowa, as the Video Game Capital of the World.

As Twin Galaxies continued to rank top players, the first national video game team was formed to represent the United States, made up of a select cadre of the very best talent. It was called the U.S. National Video Game Team, and Day, as the founding team captain, issued international video game challenges to Japan, the United Kingdom, and Italy, even hand-delivering proclamations to their respective embassies in Washington, DC. Eventually, the team toured the United States, Europe, and Asia during the 1980s.

By 1985, Twin Galaxies had enjoyed major media coverage in *LIFE* magazine, Marvel Comics, the *Wall Street Journal*, *USA Today*, *Stern* magazine, and the *Washington Post* and had had nearly one hundred TV appearances, including ABC-TV's *Entertainment Tonight* and *NBC Nightly News*. As Twin Galaxies' fame spread further, Walter Day was designated an assistant editor in charge of video game scores for the 1984–86 editions of the U.S. edition of *The Guinness Book of World Records*. After Guinness World Records decided to cease coverage of video game scores in its books, Twin Galaxies, under Day's direction, wrote the first official rulebook for playing electronic games and established the rules and standardized settings for each game. Today, this rulebook has evolved into Twin Galaxies' most well-known product: *Twin Galaxies' Official Video Game & Pinball Book of World Records*, a two-volume edition totaling fifteen hundred pages and containing scores from players in thirty-one countries that had been compiled since 1981. Guinness World Records officially recognized Twin Galaxies as the authority on all video gaming scores and records and, in 2008, began

importing its database of champions into the annual *Guinness Gamer's Edition*, a book highlighting myriad video gaming scores and achievements.

By the turn of the millennium, Day would find himself considering retirement as well as attempting another passion, creating his own music. In 2006, successful business owner Pete Bouvier became involved with Twin Galaxies, and at the start of 2007, he became the CEO and owner operator of the company under its new name, *Twin Galaxies International*. Bouvier has transformed the company into a professional services organization that is called on to adjudicate video game world records and facilitate contests and tournaments for major gaming companies. The company employs a worldwide staff of referees and writers, allowing it to cover video gaming events happening all over the globe.

In 2014, Jace Hall became the new owner of Twin Galaxies, and a new website for the company appeared in April of that same year. The website includes discussion for a high score database.

Today, Twin Galaxies International is recognized as the world's premiere electronic games referee, providing governance for the video gaming industry. It covers arcades, home consoles new and old, computer games, pinball, handhelds, and portables, and it will be tracking mobile phone gaming in the near future. Twin Galaxies International sets and enforces the rules for gameplay, validates and retains the scores and achievements, and maintains the integrity of fair play across the sport of competitive video gaming.

In the foreseeable future, Twin Galaxies International has plans to release the first trading card set of video gaming

champions from across the globe, and it will begin issuing licenses to gaming establishments, enticing players to visit and attempt world record scores. As previously noted, it will also begin tracking scores on one of the newest video gaming platforms that has really gained a foothold in the market: mobile phones. The company will also continue to have a major presence at the Big Bang event held annually at the International Video Game Hall of Fame located in Twin Galaxies' birthplace, Ottumwa, Iowa.

Twitch

Founded in June 2011 as a spin-off of Justin.tv, Twitch (also known as Twitch.tv) has become the major livestreaming video platform and is now owned by Twitch Interactive, a subsidiary of Amazon.com. The platform is mainly used for video game livestreaming and esports competitions. It gets its name from *twitch gameplay*, a style of fast gameplay that tests players' reflexes and quick reaction times.

After being spun off from the general-interest platform Justin.tv, Twitch was established as a separate platform and supported by venture capitalists who invested \$15 million in 2012 and \$20 million in 2013, after which Twitch became profitable. After that, Twitch became the dominant venue of the esports boom,

broadcasting most major tournaments. Twitch was so important to esports that it was integrated into the hardware of the Microsoft Xbox One and the Sony PlayStation 4, and this has led some critics to suggest that it has a near monopoly on the market (Popper 2013).

By mid-2013, Twitch's user base had grown to around forty-three million unique visitors a month, and in August 2014, Amazon.com acquired Twitch Interactive for \$970 million. In December of that year, Twitch acquired GoodGame Agency, the owner of two esports teams, the Seattle-based team Evil Geniuses, who won the International 2015 (an annual *Dota 2* [2013] championship), and the Swedish team Alliance, who later left GoodGame Agency to become a player-owned team in 2016.

Twitch has also broadcast professional sports, including the G League games of the National Basketball Association (NBA) since 2017, and the following year, Twitch featured some Thursday Night Football games in an agreement with the National Football League (NFL).

Since its first event in 2015, Twitch has also run TwitchCon, an annual convention for Twitch users that promotes the platform and video livestreaming. In April 2017, Twitch also launched an Affiliate Program that allows fans to support streaming channels. At the start of the program, affiliates were required to have at least fifty followers and five hundred minutes broadcast, seven unique broadcast days, and an average of at least three concurrent viewers, all within the last thirty days at the time of application (Fontaine 2017).

Although blocked in China as of September 2018, Twitch remains the dominant video game streaming platform in

the rest of the world and is well positioned to remain an influence on the further growth of the esports industry.

U

Ubiquitous Games

Ubiquitous games extend the alternate worlds of video games into the physical world by taking the gaming experience into everyday spaces and contexts. Players interact with ubiquitous games across multiple media platforms, from clue-embedded websites and documents hidden on servers to mobile phones, global positioning systems (GPS), phone booths, classified advertisements, billboards, and so forth. Rather than the space of the game being confined to a computer-generated world, ubiquitous games consist of both virtual and actual locations that the game's designers may or may not designate in advance as the playing fields. The designers may limit the time of play to a certain period, or the game may have no set temporal parameters. These types of games are related to, and sometimes synonymous with, pervasive games and alternate reality games (ARGs); ubiquitous games, however, take explicit cues from the philosophy of ubiquitous computing.

Some examples of ubiquitous games include *Can You See Me Now?* (2001) from Blast Theory and Mixed Reality Lab, *PacManhattan* (2004) by Frank Lantz and his students, and *I Love Bees* (2004) by 42 Entertainment. In *Can You See Me Now?*, participants from around the world played the game in an online virtual version of the city of Sheffield, England, although other participants used handheld computers to track the

locations of the online players and chase them through the actual streets of the city. The online players used GPS technology to evade the runners in the streets. In 2004, Frank Lantz and his students at New York University's Interactive Telecommunication graduate program designed a version of the iconic *Pac-Man* (1980) video game that would take place on a grid of streets around Washington Square Park in New York City. In *Pac-Manhattan*, a player dressed like Pac-Man runs through the streets attempting to collect all of the "dots," with four players dressed as the ghosts in pursuit. The players, equipped with mobile phones, keep in contact with a person in the control room, who updates the location of the player through mapping software. *I Love Bees* was created for Microsoft's launch of the video game *Halo 2* in 2004, and the URL ilovebees.com appeared in theatrical trailers for *Halo 2*. When players visited the site, they found what appeared to be a website about beekeeping that had been hacked by artificial intelligence (AI). Following clues that were released over a few months on the website, players were directed with GPS coordinates to pay phones, where they listened to chapters of a *Halo*-related audio drama that eventually revealed more clues and the solution to the mystery.

Although ubiquitous games can range from art projects to viral marketing campaigns, they all share the common theme of finding pleasure in interweaving the game world into the physical world.

Similarly, ubiquitous computing seeks to decentralize the personal computer as the site of computing and to extend the interface into unexpected and everyday objects, such as clothing, buildings, and items in the supermarket. Transforming the banal into the fantastic, ubiquitous games follow this logic by embedding game elements into nongame objects and into the everyday lives of players. Ubiquitous games also share similarities with urban games played by the Situationists, an international group of writers, artists, and theorists associated with European avant-garde art movements and Marxism. In the mid-twentieth century, the Situationists played elaborate games in public urban places to create alternative spaces in everyday life for the articulation of desires that countered capitalist conditions. The deliberate amplification of gaming beyond the magic circle in ubiquitous games emphasizes the idea that we already live in a game-infused culture and speak of many aspects of life as games to be played.

Ubisoft

Ubisoft, properly named Ubisoft Entertainment SA and formerly Ubi Soft Entertainment SA, is a French video game company. Originally based in Carentoir (French Brittany), the Guillemot family sold agricultural supplies and equipment for local farmers. Every child in the family, following their mother's will, went into business studies or got a university degree in economics: Claude (born in 1956) and Michel (born in 1959), at EDHEC (Écoles des hautes études commerciales); Yves (born in 1960) at IPME (Institut de la PME); Gérard (born in 1961) at EBS (European Business School); and the youngest, Christian (born in 1966), followed an economics program at the University of Rennes. All of them worked for the family business during their youth and learned how to manage marketing, sales, and accounting.

At the end of the 1970s, the family business faced difficulties and had to choose a new sales market. The oldest of the brothers diversified the original business to include computers, professional software sales, and even audio CDs. Guillemot International Software, founded in 1984 and headquartered in La

Gacilly (French Brittany), worked as a mail-order seller and then as a wholesaler, shipping British software and computers to the French market. Identifying video games as a growing market, the Guillemot brothers founded Ubi Soft on March 28, 1986, and established its new headquarters in Créteil, in Paris's suburbs.

The first video game published by Ubi Soft, *Zombi* (1986), was inspired by George A. Romero's *Dawn of the Dead* (1977). Many of the first Ubi Soft titles took inspiration from popular movies, such as *Manhattan 95* (1986), after John Carpenter's *Escape from New York* (1981), with a hero named Snail Lispken, or *Peur sur Amityville* (1987), after the movie *The Amityville Horror* (1979). Ubi Soft also produced heroic fantasy and role-playing games (RPGs), with a series named *Le logiciel dont vous êtes le héros*, after the French gamebook collection *Le Livre dont vous êtes le héros: Fer & Flamme* (1986), *Le Nécromancien* (1987), *L'Anneau de Zengara* (1987), and *Le Maître des âmes* (1987). And like other French publishers, Ubi Soft adapted Franco-Belgian comics (*bande dessinée franco-belge*), including Franquin's *Gaston Lagaffe* and Italian comics such as Tanino Liberatore's *RanXerox*. The company published titles created by experienced authors coming from French concurrent companies, such as FIL and Rainbow Production. Ubi Soft also signed distribution deals for its own titles to be released in Spain and West Germany as it started importing games, such as Elite Software's *Commando* (1985) and its port of SNK's *Ikari Warriors* (1986), for distribution in France.

During the years 1987–88, Ubi Soft experienced new production management

in château de La Grée de Callac, a castle near Monteneuf in French Brittany. To supervise game coding, facilitate technical exchanges between programmers, and ensure project deadlines, Ubi Soft gathered young people to create development teams. For a few weeks, often in the summer, programmers were fed and housed to remain focused on a game's production. This established a new publishing model in France—differing from the standard model where an author proposes a game to a publisher—an integrated model, where a publisher assumes production costs and the game programmers' salaries. At the time, Ubi Soft began to work with American publisher Epyx.

In 1988, Yves Guillemot became Ubi Soft's chief executive officer and relocated activities to Montreuil in 1994, establishing a studio with over one hundred employees. Targeting video game console markets such as those of the Atari Jaguar and Sony PlayStation, *Rayman* (1995), created by Michel Ancel, was released in 1995 to critical and commercial success and a worldwide audience. In the 1990s, Ubi Soft began its international expansion, raising funds in 1996 through a stock market launch and establishing worldwide development studios in Annecy (France, 1996), Shanghai (China, 1996), Montreal (Canada, 1997), and Milan (Italy, 1998).

In the 1990s, Ubi Soft produced games as French comedy tie-ins (e.g., for Luc Besson's productions) and then, in the 2000s, Hollywood movie tie-ins for films that included Disney's *Dinosaur* (2000), DreamWorks Animation's *The Road to El Dorado* (2000), and multiple Sony Pictures Animation films as well as blockbusters and action movie adaptations, such as McG's *Charlie's Angels* (2000)

and Tim Burton's *Planet of the Apes* (2001). The adaptations of Peter Jackson's *King Kong* (2005) by Michel Ancel and James Cameron's *Avatar* (2009), developed in Montréal, were the most important tie-in projects carried out by Ubi Soft at the time, the latter having disappointing sales results. In December 1999, Ubi Soft cofounder Michel Guillemot took aim at the mobile games market by founding Gameloft SE.

On September 9, 2003, Ubi Soft simplified its name to Ubisoft and introduced its new logo, known as "the swirl." In the 2000s, Ubisoft also began to develop its own successful video game franchises, including *Prince of Persia*, *Assassin's Creed*, *Far Cry*, *Just Dance*, *Raving Rabbits*, and multiple Tom Clancy franchises, including *Rainbow Six*, *Ghost Recon*, *Splinter Cell*, and, in the 2010s, *The Division*. At the same time, Ubisoft continued to collaborate with French authors, such as Michel Ancel (*Beyond Good & Evil* [2002]), Eric Chahi (*From Dust* [2011]), and Yoan Fanise and Paul Tumelaire (*Valiant Hearts: The Great War* [2014]). In 2011, Ubisoft Montpellier developed UbiArt Framework, a 2.5-D video game engine used for *Rayman Origins* (2011), a platformer reboot, and other artistic projects, including *Child of Light* (2014). Ubisoft also developed other tools, such as the game engine AnvilNext, for the *Assassin's Creed* series, and the Dunia Engine, for the *Far Cry* series, as well as the digital distribution, digital rights management, and multiplayer service Uplay.

Ubisoft faced hostile takeover attempts in the 2000s and 2010s, first by rival company Electronic Arts (EA), which purchased a 19.9 percent stake in the firm in December 2004. EA ended up selling the

shares in 2010. In 2015, Ubisoft was targeted by French media company Vivendi, which was attempting the acquisition to expand its media properties. Vivendi acquired stakes in both Gameloft, an Ubisoft sister company, and shares in Ubisoft. Fearing a hostile takeover, Yves Guillemot asked for Canadian investors and raised the family stake in Ubisoft more than 13 percent and the assured voting share to 20 percent. Vivendi continued to buy shares in Ubisoft, gaining 23 percent in September 2016, then holding a 27.15 percent stake in Ubisoft. On March 20, 2018, Ubisoft and Vivendi negotiated a deal ending any potential takeover. Vivendi sold its shares by March 2019. Chinese company Tencent then purchased shares in Ubisoft.

Since 2000s, Ubisoft has become one of the largest video game publishers after Activision Blizzard, EA, and Take-Two Interactive in terms of revenue and market capitalization, and it claims to have one of the largest in-house development team, with more than fourteen thousand employees working in over forty studios. The company set up the in-house studios Ubisoft Montreal, Ubisoft Toronto, Ubisoft Bucharest, and Ubisoft Shanghai, and it also acquired several studios across the world, such as Massive Entertainment (Sweden), Red Storm Entertainment (United States), Reflections Interactive (England), and RedLynx (Finland).

Ultima Series

The *Ultima* series is one of the longest-running computer game franchises of all time. It consists of both single-player fantasy role-playing games (RPGs) and the massively multiplayer online role-playing game (MMORPG) *Ultima Online* (1997) as well as their multiple expansion packs. Launched by then fledgling game designer Richard Garriott in 1980, when Garriott was still a university student, the series is now owned by major game developer and publisher Electronic Arts (EA). Although the single-player *Ultima* games were widely credited with pioneering the computer game genres of the RPG and the graphical adventure game, *Ultima Online* has been lauded for popularizing the MMORPG and, in so doing, introducing an entire generation of players to the experience of residing in and navigating a persistent multiuser virtual world. On the whole, the series has been acclaimed for the open-endedness of its gameplay, the degree of choice it allows players in terms of customizing character appearance, capability, and morality and the detailed expansiveness of its game world. Although a new single-player version of the series has not been produced since 1999, at the time of this writing, EA has continued to maintain and update *Ultima Online* through multiple expansion packs and client upgrades, and, despite having been surpassed by more recent MMORPGs in terms of popularity, *Ultima Online* still retains a dedicated user base.

From its inception, the *Ultima* series was instrumental in adapting the rules, gameplay, and fantasy settings of the tabletop RPG (embodied most famously at the time by *Dungeons & Dragons* [1974]) to the realm of the computer game, helping to shape the RPG into one of the most robust computer game genres of all time. Although their specifics vary from game to game, computer RPGs typically allow players to create and customize a developed character persona defined by such traits as species, race, gender, and occupation as well as abilities, such as strength and dexterity, which tend to be highly relevant to gameplay (Wolf 2005, 202). Following the success of the first graphical adventure game, *Adventure* (1979), the *Ultima* series was also one of the first graphically based adventure game series, wherein player characters may move somewhat freely through the (usually fantastic or historic) settings of the game world, pursuing multistep objectives typically more complex than simply shooting, evading, killing, or catching one's opponent (Wolf 2005, 196). Unlike text-based adventure games that relied on written descriptions to convey the action of gameplay, *Ultima* utilized graphics, including on-screen controllable characters and navigable digital spaces, which, despite their initial simplicity, heightened the player's sense of immediacy in the game action. It was also the first home computer game to permit scrolling in both vertical and horizontal directions, allowing players to move through a larger playing field than what could be viewed on-screen at any given time (Wolf 2007, 83).

The first *Ultima* (California Pacific, 1980) set the basic template for the series by enabling a high degree of flexibility

for players in creating their characters, allowing them to choose different fantastical races and classes, each with its own special abilities and shortcomings. Player characters moved through the game's fictional medieval world, gaining character-enhancing experience points through successful battles and ostensibly moving toward the goal of defeating an evil warlord who had enslaved the kingdom. However, rather than being forced to adhere to a strictly linear quest structure, players could go about achieving this goal in different ways and had some freedom to explore the various landscapes and dungeons of the game world. Players also had to manage such mundane resources as money and food in the process. On the whole, Garriott has described his game design philosophy as being world focused rather than story focused, suggesting that the story of each of the games in the single-player RPG series is meant to showcase the world of the game rather than a specific sequence of narrative events. Garriott has cited J. R. R. Tolkien's exhaustively realized Middle-earth as one inspiration for this approach (Kolbert 2001).

Ultima II: Revenge of the Enchantress (Sierra On-Line, 1982) innovated gameplay by allowing player characters to talk to non-player characters (NPCs), and its packaging also featured a detailed cloth map of the game world, which would become a trademark of subsequent *Ultima* releases. Garriott and his brother Robert used the money earned from the first two *Ultima* games to create Origin Systems, which would publish *Ultima III: Exodus* (1983) as well as all the remaining titles in the series, until Garriott sold Origin to EA for \$30 million in 1992. Besides introducing the ability to

create and guide a multiperson party through the game, *Ultima III* was also noteworthy as the last game in what had been dubbed the "Age of Darkness" trilogy in the series. The subsequent three games (*Ultima IV: Quest of the Avatar* [1985]; *Ultima V: Warriors of Destiny* [1988], and *Ultima VI: The False Prophet* [1990]) would make up the highly successful "Age of Enlightenment" trilogy, which refocused the role-playing elements of the series somewhat to facilitate a greater emphasis on morality, with players able to choose a player class that reflected their own moral views and possessed different virtues (including compassion, honesty, and justice) that would be mobilized in the course of gameplay. The acclaimed, two-part *Ultima VII* (*Part I: The Black Gate* [1992] and *Part II: Serpent Isle* [1993]) shifted the series toward real-time combat on the battlefield (versus the turn-based combat of its predecessors), with the last two games in the series (*Ultima VIII: Pagan* [1994] and *Ultima IX: Ascension* [1999]) downplaying role-playing elements somewhat in favor of foregrounding action-based combat and adventure game mechanics. The long-delayed *Ultima IX* was widely considered a costly failure and has been blamed as a contributing factor in the demise of the single-player facet of the series.

Although the single-player *Ultima* games wound down in the late 1990s, *Ultima Online*—the fantasy MMORPG launched by Origin and EA in 1997—moved the series into an entirely new realm of both commercial popularity and cultural significance. *Ultima Online* took the vast medieval storyworld of the single-player series and moved it into a visually lavish, persistent online multiuser

environment. Although it maintained the series' role-playing roots, as per the new demands and possibilities of its persistent online nature, gameplay became decidedly more open-ended and directed toward a greater diversity of tasks, ranging from heated player-versus-player (PvP) confrontations and real-time combat to the minutia of decorating an avatar's home and wardrobe. As such, it demanded a high degree of personal investment from players, fostering a greater sense of immersion in (and commitment to) the game world. For many players, this commitment entailed spending more time in the *Ultima Online* game world than they had in any previous game and, in some more extreme cases, becoming almost as invested in their virtual lives as they were in their real ones.

As T. L. Taylor (2006) has pointed out, while *Ultima Online* was not the first graphical multiuser game world to blend the long tradition of text-based online multiplayer games such as MUDs with graphical visual spaces—*Meridian 59* (3DO, 1996) and *Diablo* (Blizzard, 1996), for example, allowed users to enter into a graphical space and play with others in real time—*Ultima Online* tends to be seen as the breakthrough game of the MMORPG genre because of its intense and almost immediate popularity, its success in creating a rich and fully realized game world, and the lively player culture it cultivated. Despite struggling with multiple system crashes during the initial mass influx of players, it quickly reached and surpassed the one hundred thousand subscribers mark, far surpassing the player populations previously seen in multiuser domains (MUDs) and other graphical worlds. In addition to their investment in the original game

software, each player paid \$9.95 per month to maintain access to the game, demonstrating to other game companies how the online subscription model of the MMORPG could be highly lucrative.

Ultima Online also raised and confronted many of the key issues still faced by MMORPGs to this day, including community management, mass player protest, and “griefing” (intentionally disruptive play), as well as the challenges of managing a “real” economic system in a virtual world. For example, *Ultima Online* was the first MMORPG to allow players to buy and sell virtual in-game objects for real money, a practice that has continued and flourished in persistent online worlds such as *Second Life* (2003) and *World of Warcraft* (WoW [2004]). Julian Dibbell (2006) has chronicled his efforts to make a living through such transactions, contending that MMORPGs like *Ultima Online* demonstrate how the boundaries between “work” and “play” are being blurred in our increasingly networked society.

The success of *Ultima Online* spawned multiple imitators, the most famous of which, Sony's *EverQuest* (1999), quickly surpassed its predecessor in terms of both subscriber numbers and critical acclaim. However, *Ultima Online* still maintains a dedicated user base, with EA continuing to commission expansion packs and client upgrades. For example, in 2007, on the ten-year anniversary of its release, EA launched the ambitious *Ultima Online: Kingdom Reborn*, which expanded game content and sought to make its interface and graphics comparable to those of contemporary MMORPGs while maintaining the consistency of the *Ultima Online* world.

Unit Operations

Unit operations is a term used by Ian Bogost to describe how the component functions of systems produce meanings. *Units*, a nonspecific term for any discrete instantiation of some material form, are

building blocks that construct a system. These units can be as minute as the binary circuit in a light switch or as broad as an entire city power grid to which that switch is attached. Packet-switching protocols and fiber-optic lines are both units of the system of the internet. Historically received racial prejudices and statist legislation establishing racial discrimination each act as units in the apartheid system. *Operations* are any processes that perform transformative work, generating new output from input. Balancing a chemical equation, releasing a car's handbrake, apologizing to a friend, and appropriating money for health care are all operations. An operation is the logic that underlies a unit, the way it behaves.

As a framework for studying video games, unit operations offers a model for how individual components of the system that comprise the game produce meaning, both individually and together. Methods of analysis that embrace unit operations focus on the relationships between inputs, processes, outcomes, and interpretations to explain what a game is doing; *unit analysis* is the term for this practice (Bogost 2006). When we play a game, we do not discuss it in terms of a single synthesized result but rather the processes we engage with—and particularly how the processes in the game relate to processes outside of it.

SimCity (1989) offers an example. A high-level explanation of the game as a "city planning simulator" offers little in the way of saying what it means to play or what "city planning" means in *SimCity*'s case. However, by engaging the system closely at the level of discrete units in relationship to one another, we can better understand the game. Furthermore,

by understanding the game's unit operations in relation to those outside the game (such as actual city planning practices and lived experiences in cities), we can draw conclusions about the way *SimCity* works representationally.

For example, many of the rules that govern the game's mechanics are derived from Jay W. Forrester's book *Urban Dynamics* (1969). When he created the game, Will Wright implemented a simulation of a specific operational model of the city structure embedded in the software code. Understanding the individual elements—the bonuses given for building mass transit, citizen happiness, and the tax rate—determines meaning and success. The game responds as the player makes changes, sometimes hidden transparently in the underlying dynamics and other times presented opaquely in the interface. The unit operations of cellular automata and urban dynamics are related through the work that is *SimCity*.

Unit analysis can also help us understand supposedly narrative games. *Grand Theft Auto: Vice City* (2002) is not simply a playable story with a climactic ending in which Tommy Vercetti defends his position at the top of the Southern Florida crime scene. Rather, it is a game of crime missions and open-world play, both of which can be broken down even further into the mechanics that define them in relation to the worldly processes they depict.

The software-based unit operations in *GTA: Vice City* include the ability to steal cars, the rules that govern the use of weapons, the algorithms that determine police warning levels, the choice of historical and geographic setting, the relative freedom the player has to drive

around the city, the need to accept missions from characters to progress the game, pedestrian artificial intelligence (AI), the inclusion of unmarked stunt ramps, the player's inability to swim, the day-night cycle, the in-game radio stations, and so on. The configuration of these units—both within the game and in relation to external references or interpretive acts—exemplifies an analysis built on unit operations.

Hardware and software are often important when considering the meaning of a software artifact. *GTA* uses an algorithm that determines the draw distance of objects and buildings and produces a hazy landscape beyond said radius. The spawning of pedestrians and cars is governed by this distance, which means players cannot stand atop a building far away and use a sniper rifle to complete all their kill-based objectives. Likewise, the division of the game into islands is a design strategy to limit the player's mobility, but it also helps to overcome the memory limitations of the disc-based Sony PlayStation 2 hardware. The designers implemented loading screens between the eastern and western islands so that information could be read from the disc and stored memory. The code need not worry about having to draw more than a cursory skyline of downtown when the player was roaming Vice Point, so more processing power could be devoted to immediate needs. Rather than freeze the game on-screen, the developers chose to create "Welcome to Vice City" postcards for the loading screen, which provides further character to the colorful city. Because this hard stop created a break in the action, most missions do not require crossing the loading boundaries.

Bogost details first-person shooting game engines as vivid examples of unit operations influenced by hardware and software (Bogost 2006). In making *DOOM* (1993), Id Software created not only a wildly successful game but also a framework for making the genre of game *DOOM* had popularized. The technical accomplishments of *DOOM* exist both inside and outside the game; Id Tech 1, the engine that powered the three-dimensional drawing of *Doom*'s world and object interactions, became the basis of a handful of other Id Software games. While creating its next game, *Quake* (1996), Id Software set out to not only design a game but also to build an engine to be licensed to other developers that consisted of core operations. This codebase enabled the critically acclaimed *Half-Life* (1998), for example. An analysis of either game would take into account the operations of the core functions as well as what these operations enable.

United Arab Emirates (UAE)

On the eastern edge of the Middle East, Imaginations FZ, LLC, was founded in Dubai (United Arab Emirates) in 2003 and managed to create two games before it shut down in 2005: *Legend of Zord* (2003), featuring stories from the

Arabian Nights, and *Wadi Basheer* (2005), a poor racing game with a Middle Eastern twist.

The media and entertainment hub Twofour54, the representative of the Media Zone Authority of Abu Dhabi, was founded in 2008 with the aim of creating a local Silicon Valley by supporting content creation in the region. Starting in 2013, it managed to attract some major international studios; Ubisoft Abu Dhabi was established there and developed *NCIS: Hidden Crimes* (2014). However, it was extremely hard to attract the local talent, and so "investment to relocate" packages were offered, a policy that attracted many game studios that were seeking growth investments, such as Falafel Games, Tahadi, Jawaker, and Crazy Piranha.

Tahadi, based in Dubai UAE, was a major publisher of online games; it localized and operated the famous massively multiplayer online role-playing games (MMORPGs) *Runes of Magic* (2009), *Ragnarok Online* (2002), *Crazy Cart* (2009), and *Heroes of Gaia* (2010). However, unable to catch up with the rise of mobile gaming, it was acquired by Falafel Games in 2014.

United Kingdom

While the earliest British games can be traced back to chess- and checkers-playing programs in the late 1940s, it would take until the early 1970s for video games to become commercially available in the United Kingdom. Video games started appearing on the British market around 1973, when Atari opened a short-lived sales office and Magnavox began exporting its Odyssey console to Europe. The following year, homegrown ball-and-paddle home game consoles began to appear with the arrival of the Videomaster Home T.V. Game and the Videosport MK2 console created by hi-fi retailer Henry's. In 1976, the ongoing popularity of these dedicated consoles led General Instruments in Scotland to develop the AY-3-8500 integrated circuit, a generic chip with several built-in ball-and-ball games. The AY-3-8500 and its games became the basis of many of the hundreds of *PONG*-type consoles released across the world in the second half of the 1970s.

Another important development in Britain during the 1970s was the creation of the text-based online multiplayer role-playing game *MUD* (1978), short for "multiuser dungeon" (or "dimension"). Developed by Richard Bartle and Roy Trubshaw at the University of Essex, *MUD* went on to be the foremost influence on the development of the massively multiplayer online role-playing game (MMORPG) genre.

Despite these developments, video gaming in the United Kingdom largely remained limited to the consoles and coin-operated games created in the United States and Japan. However, this changed in 1980 when Cambridge-based

Sinclair Research launched the ZX80 home computer. Although basic even for its time, the ZX80 was the first home computer priced with the mass market in mind. The ZX80 and the following year's successor, the ZX81, went on to sell more than 1.5 million units. Around the same time, the country's tax-funded broadcaster, the BBC, and the UK government began a major push to encourage computer literacy among the British population that included TV programs, encouraging computer lessons in schools and the development of the BBC Micro computer.

As the wider applications of home computing remained unclear at the time, games rapidly emerged as the primary use. And with no games available to buy, many of the new computer owners started creating games themselves. Initially, these homebrew games were made available as code listings in magazines or as cassette tapes sold via mail order or at computer fairs. By 1983, retail stores were stocking games for the market-leading computers: the Sinclair ZX Spectrum, the Dragon 32, the Commodore 64, the BBC Micro, and, from 1984 onward, the Amstrad CPC. The dominance of British-made computers made it difficult for more established U.S. and Japanese computer game publishers to enter the market, allowing the United Kingdom more time to build an industry of its own.

As the United Kingdom's game industry primarily began as a by-product of self-taught computer enthusiasts rather than entrepreneurs or investors, British games of the time often reflected British cultural influences or programmers' desire to push the limits of what computers could do. Examples include the wireframe

three-dimensional galaxies contained within *Elite* (1984) and the references to the miners' strike in *Wanted! Monty Mole* (1984).

By the 1990s, however, the UK industry had become the home of Europe's biggest game publishers, such as Ocean Software and U.S. Gold. The influence of British games was starting to be felt internationally as well, thanks to the globally popular "god game" *Populous* (1989), Leicestershire-based Rare's status as a leading developer of console games, and Nintendo's hiring of London's Argonaut Software to develop its understanding of three-dimensional graphics.

The early to mid-1990s also saw the United Kingdom's choice of game hardware platforms steadily move into line with the rest of the Western world. British-made computers gave way to the U.S.-made Amiga and Atari ST and then to PCs. In parallel, home consoles started gaining significant market share. By the late 1990s, home gaming in the United Kingdom was largely divided between Windows PCs and Sony's PlayStation. The decade also saw the entire games industry undergo a process of consolidation and globalization that resulted in most leading British game publishers being bought out by better-financed foreign rivals.

While there were challenges in adapting to the costs of developing games with 3-D graphics and CD-based audio and video content, British game developers fared better producing globally significant games such as *Lemmings* (1991), *Theme Park* (1994), *Donkey Kong Country* (1994), *WipEout* (1995), *Tomb Raider* (1996), and *GoldenEye 007* (1997). However, with the video game industry now increasingly globalized and the cost of game creation rising into the millions of

dollars, UK game studios moved away from developing games heavily influenced by British culture.

Since the 2000s, the United Kingdom has remained a significant developer of video games and has been responsible for major video game series, including *Grand Theft Auto*, *Total War*, *F1*, *Batman: Arkham*, and *Fable*. Other major UK games include the LEGO games created by Cheshire-based studio Traveller's Tales and the online role-playing game (RPG) *RuneScape* (2001).

Despite this ongoing success, the number of major game studios in the United Kingdom was in decline over the 2010s. Factors behind this included the rising cost of game development, the industry's move toward free-to-play (F2P) mobile games, the impact of the global recession, and several studios that specialized in work-for-hire game development being caught out when the market for it evaporated. A further problem was the UK government being slow to follow the lead of countries such as Canada and France in providing tax incentives for video game development. The government eventually introduced tax relief in 2014, seven years after it was confirmed that such rules do not breach European Union rules. The closure of these larger studios has, however, resulted in the formation of numerous small independent and mobile game development studios that have produced notable games such as *Monument Valley* (2014) and *No Man's Sky* (2016). As such, the United Kingdom remains a major producer of video games and is the sixth-largest video game market in the world.

United States of America

As the birthplace of video games and the major producer of them (along with Japan), the United States has had a great influence on the history of video games, which have been shaped by American culture since their inception; thus, a detailed summary of video games in the United States would be a reiteration of much of that history. Since their beginning, the large domestic audience of the United States has provided enough support for the existence and growth of the video game industry, which can be divided into arcade games, console-based games, computer games, handheld games, and online video games. Although video game production companies can be found across the country, they tend to be more numerous in larger cities, such as Los Angeles, New York, and Chicago, as well

as other areas, including Silicon Valley, in California, and Austin, Texas, where game production has grown into a subculture. Many large video game-producing companies from other countries, such as SEGA, Sony, and Nintendo, also have divisions or subsidiaries headquartered in the United States.

THE UNITED STATES IN VIDEO GAME HISTORY

The 1880s through the early 1900s saw the rise of arcades as places of entertainment through the introduction of coin-operated amusement devices, including strength testers, slot machines, card machines, racing games, and other "trade stimulators" as well as the coin-operated mutoscopes and kinetoscopes that paved the way of the cinema. Early arcade video games were simple, based on action, and inexpensive to play, making them similar to much early film, which appealed to a wide mass audience of limited means and education that made up a significant percentage of the American public around the turn of the century. One of the most popular types of games to emerge from the arcade was pinball, which became electrified and grew in popularity from the 1930s to the 1950s. Other electromechanical games, housed in upright cabinets, provided the format that would be adopted by arcade video games.

Advances in computer technology after World War II led to many universities housing mainframe computers on their campuses, and experiments on these led to mainframe games. By the 1960s, when the children of the postwar baby boom were reaching college age and experiments in art and computer technology had spread

to many campuses, the stage was set for the emergence of video games on main-frame computers, and games such as *Spacewar!* (1962) arose as the result of hacking. During this time, American inventor Ralph H. Baer received a patent for the idea of home video games, resulting in the production of the Magnavox Odyssey in 1972. Also in the early 1970s, *Spacewar!* and Baer's tennis game were adapted by other parties into arcade video games (such as *PONG* [1972], the first hit arcade video game), which were housed in upright cabinets and used arcades as their main venues. The large number of baby boomers, responsible for the growth of youth culture during the 1960s and afterward, and the generation that followed them became the main audience for video games and encouraged their growth in arcades and in the home during the 1970s, when the American game company Atari became dominant in the industry.

Home computer technology of the late 1970s and early 1980s resulted in the rise of home computer games, amateur computer game programming, and homebrew games as well as networked games on bulletin board systems (BBSs) and multiuser domains (MUDs). The rise of blockbuster cinema during this time, along with the development of the franchising and merchandising of popular film and television shows, led to video games that were adaptations of content from other media, and in the 1980s, the video games themselves became the source of character-based franchises that spread to other media (such as those involving *Pac-Man*, *Mario*, and *Zelda*).

After the video game industry crash of 1983, Japanese video games gained prominence with Nintendo of America's introduction of the Nintendo Entertainment

System (NES) in 1985. The NES was a version of Nintendo's Famicom system that was released in Japan, which Nintendo reworked specifically to appeal to American retailers, who were wary of new game systems after the crash. The United States would continue to be the leader in the area of home computer gaming due to the domination of IBM, Microsoft, and Apple in the computer industry, although these, too, would find growing international competition. The late 1980s saw the growth of online games, which were becoming available for more and more participants, and they blossomed into massively multiplayer online role-playing games (MMORPGs) a few years after the World Wide Web went worldwide in 1993.

By the early 1990s, advances in computer technology led to, and were encouraged by, the use of computer graphics in all areas of American visual media. Three-dimensionally rendered graphics and photo-realistic textures and lighting allowed computer-generated imagery (CGI) to be integrated into live action, bringing video games and other media ever closer together. Other rapidly growing technologies, such as cell phones and handheld computing devices, opened up new venues for video games, as Americans spent more time commuting and on the move. Most of these venues would be exploited in the following decade, resulting in the popularity of mobile gaming and casual games in the 2000s. The year 2001 would see another American company enter the home console race, with the appearance of the Microsoft Xbox. By the 2010s, the original generation of video game players were nearing retirement age, and video game players could be found across all demographics, which

was reflected in the enormous variety of games and game venues.

THE CHARACTER OF AMERICAN VIDEO GAMES

With the wide variety of video games in existence, it is difficult to argue for a cultural resemblance among them all that stems from American cultural values; however, a few broad generalizations can be suggested. First, the highly competitive nature of American society makes for fertile ground for competitive gaming, and it should be no surprise, then, that the majority of video games are competitive ones (as opposed to other styles of play, such as cooperative play or sandbox-style play, which could have become the dominant one but did not). Competition is often involved with the acquisition of goods, property, and position (which at various levels in American culture has resulted in consumerism, materialism, and imperialism), and equivalent activities in video games include the collecting of objects or points and the attaining of high scores or higher levels within a game.

Other noted aspects of American culture, such as its relative extroversion, inventiveness, pioneer spirit, and appetite for novelty, are also apparent in many of the games developed in the United States as well as in the way American game companies are run. Besides competition and acquisition, other themes—such as cultural conflict and development of identity—could be said to correspond to similar concerns in American society. The growing variety of video games and the venues for them ensures that video games will find ways to connect to the culture they are embedded in, and it

seems likely that video games will remain an integral part of American culture.

Universal City Studios, Inc. v. Nintendo Co. Ltd.

Donkey Kong was originally released in Japan on July 9, 1981, and quickly became a hit in North America (*Nintendo of America* 1982). On June 29, 1982, Universal's lawyers filed suit against Nintendo (*Universal City Studios* 1986). The film *King Kong* (1933) and the video game *Donkey Kong* are both about a giant gorilla who kidnaps a blonde woman and carries her to the top of a tall building. Universal Studios thought this made *Donkey Kong* too similar to *King Kong*, and so, in the spring of 1982, Universal took Nintendo to court, claiming that *Donkey Kong* infringed on its *King Kong* trademark. Despite the clear similarities,

Universal lost the case and was eventually forced to pay Nintendo approximately \$1.5 million (*Universal City Studios* 1986). To understand why Universal lost the lawsuit, it is necessary to understand the complicated history of *King Kong*.

King Kong was first released by RKO Pictures in 1933. Before the movie was released, the screenwriters released a *King Kong* novel to generate publicity for the movie, and the copyright on this novel eventually fell into public domain. In the 1970s, Universal intended to make a new movie starring King Kong, but when RKO sold the rights to a rival company, Universal sued for the right to make its own King Kong movie (*Universal City Studios* 1986). During this lawsuit, Universal claimed that because the *King Kong* novel was in the public domain, it could make a movie based on that book without RKO's permission. The court agreed with this argument but stipulated that only the material in the novel was in the public domain. Because of this, RKO still owned “‘the copyrightable matter’ which was contained in the 1933 movie but not in the original novel” (*Universal City Studios* 1986). Years later, perhaps in an attempt to gain some ownership over King Kong, Universal bought the trademark of the name “King Kong” from the son of the novel's author (*Universal City Studios* 1986).

Therefore, Universal may have owned the name “King Kong,” but no one owned the idea of a giant ape; it was RKO, not Universal, who owned the famous elements of the King Kong story, such as Kong kidnapping a blonde woman and taking her to the top of a tall building—which were exactly the elements that Universal argued *Donkey*

Kong and *King Kong* held in common. This meant that Universal had no case. The judge dismissed Universal's case against Nintendo and forced Universal to pay Nintendo's lawyer fees and damages.

Unlockable Games

Unlockable games are those made available to a player within a “parent” game through the satisfying of one or more particular conditions within that game. Such conditions can include completing the parent game once or more, achieving a certain level of competence, collecting a certain number of in-game bonuses, or even just discovering an Easter egg that makes the unlockable game available for play. Unlockable games typically pay homage to the parent game or the company responsible for the parent game's creation. As such, newer iterations in particular game franchises will often

offer unlockable versions of their predecessors.

Examples of games that house unlockable games include *Animal Crossing* (2001) for the Nintendo GameCube, which contained a series of Nintendo Entertainment System (NES) games, such as *Balloon Fight* (1984) and *Ice Climber* (1985; see “Retrogaming”), that a player could make available through a number of methods, such as entering an in-game lottery to “win” the games as prizes. In the indie game *Celeste* (2018), a player can even discover and play an original prototype of the game, dubbed *Celeste Classic*, on a computer in an in-game resort’s back office.

Unlockable games can either be games that are smaller in scope than the parent title (see Minigames) or full-featured, previously stand-alone games. However, older games included as unlockable games are frequently considered minigames simply because of the relative difference in scope, length, style, and difficulty of play compared to more contemporary titles.

Unlockable games are similar to but should not be confused with *unlockable modes*—levels, difficulties, or minor variations on a game’s preexisting goal structure that are made available to a player after he or she meets certain conditions in the game. An ideal example of an unlockable mode is the “Challenge of the Gods” in *God of War* (2005), which changes the linear scenario presented by the game’s core mode of play, pitting a player against several rounds of oncoming enemies in an enclosed arena. This mode is only made available after the game has been played through once.

Finally, a game demo may allow the unlocking of the full version after the input of a serial key or some other form of

purchase validation. Game demos such as those downloaded on a downloadable content (DLC) network (e.g., Xbox Live) often allow a user to download all of a game’s files while only having feature-limited access to the game’s content. Full access to such games only becomes available for feature-complete play after validation, thereby “unlocking” the remainder of the game’s content. One example of this is Square Enix’s *Octopath Traveler* (2018), which allowed the free download of a version of the game for all users. This version allowed players to save several hours of progress with their in-game character, but upon hitting the play limit, it prevented further play until a player purchased the full game. Only after unlocking the full game’s content through purchase could a player continue play with his or her saved data.

Unreal Engine

The Unreal Engine is a game engine developed by Epic Games that was initially released in May 1998. It is a source-available engine commercial software, with a royalty model for commercial use, and was mainly oriented toward first-person shooting games, even though the

last versions are more diversified (the engine also became the basis for a number of role-playing game [RPG] titles, including *Mass Effect* [2007]). The engine's main competitor is Unity (and CryENGINE from Crytek, to a certain extent). The engine's current release is Unreal Engine 4; version 4.20 was released on July 16, 2018.

The Unreal Engine's first generation was developed by the founder of Epic Games, Tim Sweeney (and around sixteen other developers). A fan of Id Software's *DOOM* (1993) and *Quake* (1996), Sweeney wrote a program to create a graphic shell that would allow for a visually high-quality and realistic game environment. The first technical improvement was to switch from 8-bit color (256 colors) to 16-bit color (65,536 colors). After eighteen months of work, a stable version was produced in 1994. The powerful graphic engine, with an optimized rendering system, was called "Unreal" by Tim Sweeney and James Schmalz and was published by GT interactive on May 22, 1998.

Another decision that led to the Unreal Engine's success was the creation of an easy-to-use editor to simplify the level-creation process that would actually include the 3-D game engine: building the tools and game engine together in an editor was one of the key selling points of the product compared to those of competitors. Many special effects were also added due to an unseen physics engine. The Unreal Engine debuted in *Unreal* (May 1998) and was also used in *Unreal Tournament* (November 1999). Soon afterward, the Unreal Engine became the main competitor to Id Software's Quake II engine.

When *Unreal* was released in May 1998, the game was well received by specialized press and the gaming community. However, some gaps and technical issues on the network/multiplayer mode tarnished the game's growing reputation. Epic Games developers created an official extension to correct those issues and to upgrade the network code to optimize multiplayer gameplay. They finally drastically upgraded the rendering system to four times the level of detail (especially on the character's faces). This enhancement was well developed and led to the game *Unreal Tournament*.

At the beginning, Unreal Engine was written in C++ (around 350,000 lines code) and a scripting language called UnrealScript (often abbreviated to UScript and used for 90 percent of *Unreal Tournament* gameplay). UnrealScript was created by Tim Sweeney for programming high-level game concepts provided by the Unreal Engine. It was designed as a strong and simple language and inspired by Java (but without object wrappers for primitive types). However, UScript is twenty times slower than C++, but with low processor use, and is object oriented. It includes native support for time, state, and network replication, which greatly simplifies game programming.

Thanks to its strong object-oriented design, the Unreal Engine is extremely modular: programmers can make massive changes to parts of the game without affecting other features and without affecting source code. Each subsystem is connected to other subsystems through a clearly defined interface, and platform-specific code is consigned to separate libraries. Moreover, the engine's modularity is implemented in the engine's script

A programmer using the Unreal Engine. (Savconstantine/Dreamstime.com)

language. Weapons, pickups, level events, AI nodes, and other world actors are all independent objects.

Unreal Tournament's modular package system, coupled with Unreal Editor, makes the game a mod-creation system out of the box, designed to be able to allow additional extensions by gamers, amateur artists, and programmers in recognizing the value of the mod community.

In the Unreal Engine, the world is full at the beginning, and the designer uses it to create the game's universe. This allows the designer to use "portals" to partition his world into very distinct closed zones and offers the possibility, thanks to the potential visibility sets (PVS), to display only the visible parts. Thus, the Unreal Engine allows for intricate interiors and rich exteriors while delivering impressive performance for its time. For the "sky" (the dome above gameplay), Epic adopted the *skybox* system, which is a common

process today to represent the sky in real-time 3-D.

Unreal Engine was intended for PlayStation consoles, Dreamcast consoles, and PCs from the late 1990s. Similar to what Id Software did with the Quake Engine, Epic Games made the Unreal Engine 2.0 available under license. Especially popular in the mod developer community, it quickly became the main competitor of the Quake Engine. In addition to titles developed by Epic Games and Digital Extreme, it has been used by many development studios in such games as Ion Storm's *Deus Ex* (2000), Electronic Arts' *Harry Potter and the Philosopher's Stone* (2001), Human Head Studios' *Rune* (2000), and the Collective Inc.'s *Star Trek: Deep Space Nine: The Fallen* (2001), among others.

With the development of Unreal Engine 2, Epic Games chose to broaden its market and made the new engine compatible

with the Microsoft Xbox, PlayStation 2, Nintendo GameCube, Nintendo Wii, and SEGA Dreamcast. Home computers were also quickly evolving, but Epic Games wanted its engine to work in both worlds. Unreal Engine 2 was an attempt to build a shared tool that would make multiplatform development possible. The first published title based on Unreal Engine 2.0, and not done internally, was *America's Army* (2002), developed by the U.S. Army and Secret Level.

Due to an agreement with Microsoft, developers had access to the Unreal Engine on Xbox, which led to the version Unreal Engine 2.X, featuring optimizations specific to the Xbox. *Unreal Championship* (2002) on Xbox, using the 2.0 engine version, was mediocre, but *Unreal Championship 2: The Liandri Conflict* (2005) used the 2.X version and met expectations with better console capacities management and visual qualities. Epic Games' licensing strategy resulted in numerous agreements with third-party studios, including Ubisoft (*Tom Clancy's Splinter Cell* series [from 2002 to 2013], including *Rainbow Six* [1998], *Rainbow Six 3: Raven Shield* [2005], etc.); Ion Storm (*Deus Ex: Invisible War* [2003], *Dark Project: Deadly Shadows* [2004]); and LucasArts (*Star Wars: Republic Commando* [2005], etc.).

Unreal Engine 3 took advantage of fully programmable shader hardware (artist friendly and programmer extensible, focused on DirectX 9). The per-pixel lighting and shadowing models were highly improved, and all rendering was done with 64-bit color HDR, according to Tim Sweeney. To compete with Crytek's CryEngine (famous for its use in *Far Cry* [2004] and *Crysis* [2007]), Epic pushed the Unreal Engine's capabilities

toward the rendering of large outdoor expanses and a higher level of realism (real-time displacement-mapped procedural support for vegetation and normal-mapped and properly lit and shadowed terrain).

Unreal Engine 3 was mainly available for PlayStation 3, Xbox 360, and PCs (and, later, iOS and other consoles). Games using it included *Gears of War* (2006), *Bioshock* (2007), *Mass Effect* (2007), *Mirror's Edge* (2008), *Batman: Arkham Asylum* (2009), *Infinity Blade* (2010; iOS version), *BulletStorm* (2011), *Devil May Cry* (2013), and *Thief* (2014), among others. Starting in November 2009, users could download Unreal Engine 3 (called the Unreal Development Kit [UDK]) on the Epic Games website, available free and without limitation for noncommercial use. Unreal Engine 4, however, would take much longer to appear on the market; development of the source code began in 2003 with only one programmer, Tim Sweeney.

On March 19, 2014, at the Game Developers Conference (GDC), Epic Games released Unreal Engine 4 through a new licensing model with a monthly price of \$19 as well as 5 percent of royalties. Since March 2, 2015, Unreal Engine 4 has been free to everyone, along with future updates. However, for commercial or for-profit creations, licensees must pay royalties. This opens a new realm for artists and independent studios who want to create new games, even with smaller teams.

Two years later, in 2016, at the GDC in San Francisco, Epic hosted a panel about its engine and its potential uses outside the gaming realm and made three big announcements. The first one included NASA speakers, who spoke about their

use of the engine to build up a “real-world holodeck,” to make Mars a virtual reality, and to create a fully functioning, perfect replica of the International Space Station (ISS) to help train astronauts in the intricacies of its systems and modules. The second announcement was by British car-maker McLaren Automotive, who used the Unreal Engine to help design and sell its high-end performance cars. Finally, the Walt Disney Company unveiled plans to use the engine to create a Star Wars–themed experience for its theme park (Star Wars: Galaxy’s Edge, which opened in 2019). Also, the Unreal Engine is growing in importance in the production of both feature films and television shows, including live shows. More recently, Epic Games used the Unreal Engine for *Fortnite* (2017), a multiplayer survival game inspired by an internal game jam.

But sometimes projects do not go as expected. *Paragon*, a multiplayer online battle arena (MOBA) game, which was to use Unreal Engine 4, was announced in November 2015, and released March 18, 2016, but it was canceled April 26, 2018. Epic Games uploaded \$17,000,000 of *Paragon* content for free to all Unreal Engine 4 developers/users who wanted to create personal projects: thirty-nine triple-A characters and over fifteen hundred environment components. All of this content is available for download inside the Unreal Engine Marketplace, a digital storefront where you can also get tutorials or purchase numerous assets.

The Unreal Engine community is made from hardcore triple-A developers but also numerous indie companies. An early version of a game like Studio Wildcard’s *Ark: Survival Evolved* (2017) was built in less than nine months. At another level, Psyonix’s *Rocket League* (2015,

2016, and November 2017 for the Nintendo Switch) had a short period to finalize a game mixing cars and soccer. Unreal Engine 4 is easily accessible and is usually preferred by artists instead of Unity because of its intuitive design and ease of use.

Released April 16, 2018, the Unreal Engine 4–powered Mars 2030 Editor brings tools used by the NASA Hybrid Reality Lab to live space simulations across forty square kilometers of open Martian terrain (available on Steam). The virtual reality (VR) experience is pushed a little bit further with that odyssey even if the pure gaming part is put aside. VR is becoming increasingly widespread within architectural design and real-time visualization, and the film industry is interested in the Unreal Engine as well. These venues and possibilities will push the engine to offer more updated powerful tools, technically and artistically.

In November 2018, the 4.21 version of the Unreal Engine became available. It included Nintendo Switch support for Niagara (the visual effects tool/plugin replacing Cascade), improvements to the assets cooking process, and numerous general improvements in rendering, networking, scripting, VR, animation, and more.

Uruguay

To talk about the development of video games in Uruguay is to immediately

recall excellent games such as *Fight'N Rage* (2019), one of the best beat-'em-up games available on Nintendo Switch, Xbox One, and PlayStation 4; educational games such as Trojan Chicken's *Special Investigations Unit* (2010) and *Ghostbusters Division*, a collaboration between Uruguay and Norway with the great ludologist Gonzalo Frasca; or Ironhide Game Studios' *Kingdom Rush* (2011), a video game with 89 percent positive reviews on Metacritic that was downloaded more than one hundred million times on iOS and was developed in seven languages: English, French, German, Japanese, Korean, Portuguese, and Russian.

The Uruguayan industry is very similar to Argentina's industry in terms of its origins and age; in Uruguay the development of video games has existed since 2002. This ecosystem was greatly favored due to the Ceibal Plan, a public policy around equity, learning, and technology. It was the first educational technology program based on the 1:1 model (one student with one computer) in Latin America, thus promoting inclusion and consolidating the integration of IT into education and learning processes.

Since 2011, the Ceibal Plan has focused on providing the educational community with a wide range of digital content for the improvement of teaching and learning processes through the development of learning management systems, educational platforms (e.g., in mathematics and English), and digital libraries, among other things, and it is from this that classrooms began to combine edutainment with ludology, taking advantage of the fact that video games are attractive because they are interactive, with adjustable difficulty; allowing students to

interact as many times as necessary with a level; and adapting the knowledge of previous learning. This policy has benefited some software development companies, both for the development of applications for XO laptops and for video games in the same operating system.

Mega events are also a sign of the growing video game industry in Uruguay. Since 2015, the GameLab (Montevideo), an international format created in Barcelona, Spain, is also held in Shanghai and Tokyo. In Uruguay, this initiative is supported by GameLab, Uruguay XXI (through Uruguay Smart Services and Smart Talent); the Ministry of Industry, Energy and Mining (MIEM); the National Telecommunications Administration (ANTEL); the Chamber Developers of Videogames from Uruguay (CAVI); Ingenio; PROANIMA; and the Uruguayan Chamber of Information Technology (CUTI).

Because of that first version of GameLab, the CAVI creation was formalized as an organization that aggregates the country's industries, and in 2017, Level Up, an official CAVI event, was created in conjunction with MIEM, DINATEL, Uruguay XXI, and ANTEL and made its first appearance with the addition of an Uruguayan game showcase, where a call was made to all developers in the country, regardless of whether or not they participated in a government event.

Uruguay is a country with a growing demand for games. In 2010, the ORT University, in Montevideo, and the Faculty of Communication and Design pioneered the offering of a degree in animation and video games. Video game training covers areas such as animation, arts and digital

media, video production, animation (2-D and 3-D), sound development, narrative, architecture, game design, characters and scenarios, programming technologies, virtual reality (VR) and augmented reality (AR), and marketing.

In 2018, digital literacy became mandatory in the schools in Uruguay and Argentina. The public policy focuses on capacity building on programming and robotics. It meets the following goals: to generate knowledge; to use technology (tablets) to fulfill educational interests; and to improve the software industry in the midterm. Despite this, the development of government computer platforms is very specific, so it is not attractive to all developers; however, there are more initiatives by the government that encourage support for video games.

As of 2019, there are twenty-two video game studios in Uruguay: ABYA, ARF Game Studio, BlitWorks, Curse Box Game Studio, EGG, Gecko Gecko Games, Golden Bite Games, the Good Guys, Ironhide, Kalio, Kef Sensei Studios, Light Arrow Games, Lisle Design, My Box, One Tango, Pincer Game Studio, Pomelo Games, Powerful Robot, Takion Studios, Trojan Chicken, Vain-sencher, and WiseShards. Also, Etermax, from Argentina, runs a branch office in Uruguay.

Vector Games

The era of vector arcade video games was a short one, beginning in 1977 and lasting less than a decade. Invented during the 1950s, vector graphics displays (also known as XY monitors) created their imagery differently from raster monitors, like those used in television sets. Whereas the electron beam covers the entire screen in raster-scan monitors, in vector-scan monitors, it only draws the line segments that make up the image and leaves the rest of the screen black. With less to draw, vector graphics could be displayed faster, with thinner, sharper lines that could be moved smoothly across the screen, as opposed to the solid, blocky graphics of raster games, for which movement was more difficult to program. Because objects were drawn individually, more moving objects were also possible, and even early vector games could have as many as forty independent objects, compared with only ten or so in raster games (Kent 2001, 130). The main disadvantage of vector graphics was that bitmaps were not available; everything was constructed from a series of line segments, so creating small, detailed graphics for game characters or objects was more difficult than it was in raster graphics. As a result, vector games tended to be less character based and mainly

consisted of wireframe imagery on a black background.

Vector graphics came to the arcade when Larry Rosenthal, who had done a master's thesis on the mainframe game *Spacewar!* (1962) at MIT, developed vector technology that could be used in arcade games, which he called the Vectorbeam monitor. Rosenthal licensed his Vectorbeam equipment to the game company Cinematronics. After a dispute, Rosenthal left the company and created his own, which he also called Vectorbeam. Both companies produced games based on *Spacewar!*; Cinematronics' was called *Space Wars* (1977), and Vectorbeam's was called *Space War* (1977). (Rather than license technology from Vectorbeam, Cinematronics later bought the company in 1979.)

Cinematronics' next release was *Starhawk* (1978), which had visuals inspired by the Death Star trench scenes in the film *Star Wars* (1977). Vectorbeam's next game, *Speed Freak* (1978), was a driving game with a first-person perspective. *Speed Freak*'s oncoming cars were three dimensional, and they resized smoothly as they approached. When the player crashed into an oncoming car, it exploded into line segments that scattered across the scene, adding a more dynamic feeling of a crash and making *Speed Freak* the best driving game of its day.

In Atari's first vector game, *Lunar Lander* (1979), players tried to fly and land a spaceship without crashing it. That same year, Atari also released *Asteroids*, which became one of the best-known vector games, exceeding seventy thousand units produced, and arcade operators had to make larger coin boxes because the game was taking in so much money. Other games of the year included

Cinematronics' *Sundance*, in which players opened panels in grids to catch bouncing suns; Vectorbeam's *Warrior*, in which two knights seen in overhead view engaged in a sword fight, one of the first one-on-one fighting games (along with SEGA's *Heavyweight Champ* [1976]); and *Tail Gunner*, a space shooting game that began development under Vectorbeam and finished at Cinematronics after it bought Vectorbeam. *Tail Gunner* was different in that its starfield movement was reversed; instead of flying into the depicted space like other games, the viewer was moving away from it, looking out the back of a spaceship at the ships chasing it—hence the name *Tail Gunner*. Exidy purchased the rights for a cockpit version of the game and released *Tail Gunner II* in 1980.

Other games of 1980 included Cinematronics' *Star Castle*, in which players fired at an enemy ship surrounded by rotating rings that could be destroyed; *Rip Off*, a tank shooting game in which pirate tanks are stealing the player's fuel canisters and hauling them off-screen; and *Armor Attack*, which featured jeeps, tanks, and helicopters from a bird's-eye view. Also released that year was Atari's *Battlezone*, probably the best-known vector arcade game of all time. *Battlezone* had a first-person perspective view and hardware that could do real three-dimensional computation.

Atari's *Red Baron* (1981) was essentially a flying version of *Battlezone* with biplanes, with rounds of shooting in the air as well as from the ground. Another Atari vector game of 1981 was the arcade classic *Tempest*, an abstract game that involved shapes moving up a well that the player had to shoot at and stop before they got to the top, an idea that began as

a first-person version of *Space Invaders* (1978; Kent 2001, 164). The scaling imagery used in *Tempest* was easy for vector graphics and was something that could not be done well in raster games. Vector games made good use of scaling and quick, smooth movement, and around 1981, they began to appear in color, including *Tempest*. Games before 1981 were typically either black and white or monochrome (e.g., *Battlezone* had green lines on a black background). Some games, such as *Star Castle*, had color overlays on the screen to make the game's lines appear to be different colors, but the monitors themselves were not color.

SEGA released two vector games in 1981, *Eliminator* and *Space Fury*. Like *Star Castle*, *Eliminator* had its enemy spaceship situated inside a circular enclosure, although *Eliminator*'s enclosure had a narrow tunnel that the player could try to shoot down to destroy the enemy ship. *Eliminator* was released in a one-player upright version, a two-player cocktail version, and a four-player version, making it the only four-player vector game ever made. *Space Fury* was another space shooting game, known mainly for its attract mode; it featured a one-eyed alien commander that taunted players in synthesized speech. Other games of 1981 were variations of shooting games, including Cinematronics' *Boxing Bugs* and *Solar Quest* and Midway's *Omega Race*.

The year 1982 was another big one for vector gaming, with at least six new arcade games appearing along with the only vector home console system. Three arcade games were from Atari: *Space Duel*, *Gravitar*, and *Quantum*. *Space Duel* was Atari's only vector game that two players could play simultaneously and

was similar to *Asteroids* but with three-dimensional color asteroids and either competitive or cooperative gameplay. *Gravitar* combined skills from *Asteroids* and *Lunar Lander* and was made up of four “universes” (with gravity that was either negative or positive and landscapes that were either visible or invisible). Each universe had three solar systems, each solar system had four or five planets, and each planet had its own unique terrain to navigate, giving players several dozen screens to see. *Quantum*, inspired by particle physics, was an abstract game in which players used a trackball controller to encircle particles (capturing them) while avoiding hitting other particles.

SEGA also had three new vector games in 1982: *Zektor*, *Tac/Scan*, and *Star Trek*. *Zektor* involved freeing eight cities from waves of attacking enemy fighters and “robot probes.” *Tac/Scan* was a three-stage space shooting game in which the player controlled a squadron of seven ships that all flew in formation and moved as one. A unique feature of the game was its change in perspective. *Tac/Scan*’s first stage was two dimensional and similar to games such as *Galaxian* and *Space Invaders*, but its second stage was three dimensional, with players firing into the screen instead of up or down the screen. SEGA’s *Star Trek* had five controls to learn, six enemies, and forty simulation levels of play, making it one of the most elaborate vector games ever made (along with possibly *Gravitar*).

The GCE/Milton Bradley Vectrex, the only home game system with vector graphics, was released in 1982. Because television sets used raster graphics, the Vectrex came with its own vector monitor. The screen was monochrome, and colored overlays were used to color the

games’ graphics. Games released for the Vectrex included original games (*Bedlam*, *Blitz!*, *Fortress of Narzod*, *Minestorm*, *Hyperchase*, and others), adaptations of Cinematronics’ vector arcade games (*Space Wars*, *Starhawk*, *Star Castle*, *Armor Attack*, *Rip Off*, *Solar Quest*, and *Cosmic Chasm*), adaptations of raster arcade games (*Berzerk*, *Pole Position*, and *Scramble*), games that used a light pen (*AnimAction*, *Art Master*, and *Melody Master*), and even some 3-D games (*3D Crazy Coaster*, *3D MineStorm*, and *3D Narrow Escape*), which involved an additional special 3-D viewer. Since the system has ceased production, Smith Engineering has allowed Vectrex materials to be copied for non-commercial purposes, allowing a community of Vectrex fans to continue creating homebrew games for the Vectrex.

A few more vector games appeared in 1983: GCE/Cinematronics’ *Cosmic Chasm*, Centauri’s *Aztarac*, and Atari’s *Black Widow*, *Major Havoc*, and *Star Wars*. In *Cosmic Chasm*, the player had to fly through tubes inside a space station to fire at its core and then fly out again before it blew up. *Aztarac*, another space game, had players defending a starbase from attacking ships. In *Black Widow*, players controlled a spider on a spider web that it defended from invading bugs by shooting at them. *Major Havoc* was a detailed multistage adventure game that involved shooting enemy ships, landing in a space station, and navigating a scrolling maze of hallways with a variety of objects (such as robot guards and electrified barriers) that the player passed through on the way to destroying the station’s reactor. Finally, the best-known vector game of 1983 was Atari’s *Star*

Wars, a colorful, three-dimensional take on the space battles and Death Star trench chase scenes from the film, and it even included digitized voice samples from the film's soundtrack.

The year 1983 was the last year Cinematronics produced vector games. That same year, it released its first laserdisc game, and its success redirected the company's efforts in the new technology. No company appears to have released vector arcade games in 1984, although work on a few games continued. In 1985, another *Star Wars*-based game, *The Empire Strikes Back*, was released by Atari Games, and it was the last major vector game released. (Only one other game may have been produced that year, Exidy's space game *Vertigo* [1985].) Probably the last vector arcade game ever made, which may or may not have been released, is Exidy's *Top Gunner* (1986), a sit-in game that is said to be a modification to *Vertigo*.

By the late 1980s, sprite technology had improved greatly, and three-dimensional filled-polygon graphics were beginning to return to the arcade after their failed debut in Atari's *I, Robot* (1984). Raster games had improved graphically, the rise of three-dimensional raster graphics games in the 1990s was just around the corner, and the era of vector games was over. However, the unique look and playing experience of vector games has attracted a following, and vector games live on as arcade collectibles and in adaptations for emulators. They are remembered as an important part of the golden age of arcade video games.

Vectorbeam

Larry Rosenthal's company Vectorbeam was the first company devoted to the production of vector games, which used vector graphics instead of raster graphics and thus could provide games with sharp wireframe graphics and smooth motion that was new to the arcade.

In the late fall of 1976, Larry Rosenthal, a graduate of MIT, along with his business associate, Bill Cravens, set up shop in Union City, California, to begin a business venture based on Rosenthal's video game success, *Space War* (1977). Before this endeavor, both men had been employed by the struggling video game company Cinematronics, with Cravens as the company's sales representative. Cinematronics was a small company located in an industrial strip mall in El Cajon, California, struggling to get by with whatever video games it could acquire and manufacture and already beginning to feel what was to come, an almost assured bankruptcy.

After graduating from MIT, Larry Rosenthal acquired the rights to build and sell his own commercial version of MIT's laboratory pastime *Spacewar!* (1962) and turned it into a coin-operated

(or coin-op) game that he called *Space Wars* (1977). His obsession with the game began in 1973, and by 1976, he was ready to put a prototype in a friend's arcade. When he returned from a short trip, Rosenthal found that *Space Wars* had taken in more than \$500 in six days, evidence that his obsession with vector displays could pay off. His next challenge was to manufacture and market the game. Rosenthal took his prototype to every established video game manufacturer that he could find, hoping one would agree to his demand for a fifty-fifty split of the revenues from the game.

Larry's faith in *Space Wars* (1977) may have appeared hubristic, but he was one of the few persons who had seen and played the original game at MIT. In an era when computer graphics were blocky and slow to refresh, vector graphics were lightning fast, faster than the flicker fusion rate, the frame rate at which sequences of moving images combine to present the illusion of continuousness. However, even with innovative features such as multiplayer gameplay, unlimited buy-in, and the allure of the game's smooth vector graphics, *Space Wars* was hard to sell to manufacturers. Even though the game was testing well, no game company was willing to split revenues with Rosenthal, except for one small, desperate company, Cinematronics. In this case, desperation became a bonanza for Cinematronics. *Space Wars* was the hit of the 1977 AMOA show and went on to sell at least ten thousand units with some sources putting the figure at three times that. Sales records of *Space Wars* put it at number one for almost two years.

With statistics like these, it was inevitable that salesman Cravens would find a

way to exploit the *Space Wars* bonanza. Rosenthal was the owner of all rights to his game, complete with patents, and his share of the revenues had become substantial thanks to the two-way split with Cinematronics. Regardless of the damage that would be done to that company, it made sense for Rosenthal and Cravens to found their own video game company, Vectorbeam. Their company did not last long, perhaps only from September 1978 to August 1980, as recorded by Vectorbeam programmer and game designer Dan Sunday. Even so, the games created there were innovative and fun to play, exploiting Rosenthal's mastery of vector graphics. The company bootstrapped itself by manufacturing its own clone of *Space Wars*, now slightly renamed as *Space War* (1977). Another slight, but significant, difference was the quality of the two company's game cabinets. Unlike the Cinematronics cabinets, which were prone to fall apart in shipment, Vectorbeam's cabinets were more solid. This was nothing significant to the players of the game, but it was a touch that helped determine which of the two versions would most likely be purchased by vendors.

The first original game from Vectorbeam was *Scramble* (1978), which is not to be confused with the later 1981 video game of the same name. Few ever played or even saw *Scramble*, an unusual and somewhat difficult-to-play vector version of a pinball game. Without the bells and flashing lights that a pinball machine offered and a playfield made up of squared-off white lines on a black background, *Scramble* had no chance of matching the fun and excitement of a tangible pinball game. Even so, Vectorbeam managed to sell enough units to

keep its new company alive. Vectorbeam programmer Dan Sunday remembers, “It was the very first game for Vectorbeam. So, when the company first started things, it was really hectic, a scramble. We were trying to get our new business off the ground and get a game to the annual AMOA show in Chicago. We managed to quickly put together the video pinball game *Scramble* and actually got it there in time for the trade show.”

Next would be a landmark driving game, Larry Rosenthal’s *Speed Freak* (1978). Unlike most driving games at the time, *Speed Freak* took advantage of vector graphics to display geometrically true wireframe depictions of oncoming cars, twisting roads, and various other obstacles and scenic embellishments. To optimize the number of lines that had to be scanned across the vector display tube, Rosenthal placed most objects on only one plane, x, y, or z. This established the true three-dimensional quality of the game without squandering precious computation and line-drawing time.

Rosenthal did, however, include one stunning animation that used all three dimensions. The biggest thrill in *Speed Freak* was rewarded not for staying on the road but for crashing the player’s car in a head-on collision. To do that, Rosenthal used all three axes to create the first true three-dimensional explosion in a video game. Because of the computation time required to rotate objects on all three axes, Rosenthal and Sunday chose to display a pre-rendered animation of pieces of the player’s car tumbling away. Even though the explosion was not interactive, it was still a landmark in video game graphics. Because of the popularity of seeing this explosion during tests,

players were allowed to crash the car without penalty until their time ran out, if they chose to do so. Many did, but most eventually went back to avoiding collisions so as to get a high score. It was customary for rival companies to play the games of other companies, and back at Cinematronics, playing *Speed Freak* became a favorite pastime.

Even though Cinematronics could still manufacture games based on Rosenthal’s hardware, Vectorbeam could still become a powerful rival. Worse for Cinematronics, the El Cajon-based company still had to pay royalties to Rosenthal for every game that used his technology, which, of course, was the only technology Cinematronics had at that time. It became obvious that Cinematronics’ best solution was to buy Vectorbeam outright. As it turned out, *Speed Freak* did well, but Rosenthal’s company was still struggling. To keep product moving on the assembly line, Bill Cravens purchased a game from Cinematronics that had only been a training exercise for novice programmer Rob Patton. At various times, it was known as *Blitz* or *Barrier* (1978), and it was never popular. In the end, Cinematronics bought Vectorbeam for \$2 million and removed its primary competitor, receiving the patents to the technology as well. This enabled the Cinematronics executives to pay themselves all related royalties, funds that would have otherwise gone to Rosenthal as part of his original agreement—not an insignificant amount.

One new Vectorbeam game, almost finished at the time of the takeover, was *Tail Gunner* (1979). This game did quite well and was eventually licensed to another manufacturer who wanted to build a sit-down version of the game. The

name *Tail Gunner* was suggested by Vectorbeam's new top executive, Tommy Stroud, the son of Cinematronics co-owner "Papa Tom" Stroud. Tommy felt that reversing the movement of the animated star field gave a greater sense of urgency to the game. He reasoned that a retreating position created greater anxiety in the player, heightening the thrill of the game. *Tail Gunner* appeared to be a certain success, but the game's joysticks had a fatal flaw. At first, the sticks appeared to be ideal; they were small, rugged, and not too expensive. What remained unforeseen was that the joysticks soon stopped working after a certain number of movements. That was acceptable for their original purposes, but they were nowhere near good enough for video games. Changes were made, but the damage was done as far as vendors were concerned. Later, in 1980, the game company Exidy licensed and sold *Tail Gunner* as *Tail Gunner II* (1980), a cockpit version using joysticks that did not have the earlier problem.

For a short time after Cinematronics' buyout of Vectorbeam, the company name became Vectorbeam, a Cinematronics Company. Release dates determined which manufacturing facility would build a particular game, regardless of where it had been developed. For instance, the Cinematronics game *Warrior* (1979) was conceived and programmed in El Cajon but was manufactured and sold from the Vectorbeam facility. The reverse was true for *Tail Gunner*, which was conceived at Vectorbeam but built and shipped from Cinematronics. This was temporary. Once Cinematronics had taken inventory, El Cajon once again became Cinematronics' only base of operations, and Vectorbeam was no more.

The last game to be associated with Vectorbeam was *Star Castle* (1980), a successful title that was a collaboration of rivals. When Cinematronics purchased Vectorbeam, Cinematronics took inventory of its rival's assets. One particular title revealed to Cinematronics was the strangely named *Oops!*; Larry Rosenthal had begun working on this game, which originally had a birth control theme. Vectorbeam programmer Dan Sunday describes the origin of this oddity:

Yes, *OOPS* existed. Part of its inspiration was that Larry was obsessed with a very attractive young lady who was playing around with him (maybe trying to dump him, but that only made Larry more obsessive about her). Anyway, he sometimes seemed more concerned about winning her than making Vectorbeam work. *OOPS* came out of this obsession. Larry had dreamed up this game where an egg was in the center of the screen, and sperm were coming on from all directions. One player controlled the sperm, and turning left caused them all to turn left, so the other player didn't really know which one you were steering. The other flew a syringe around which, when fired, would send out foam that killed the sperm. Initial tests indicated that the syringe almost always won. So, we fixed the syringe in the center of the egg and allowed the player to only rotate it.

When the delegation from Cinematronics reviewed the game that Vectorbeam had been developing, it was clear that it had potential. However, it was still a long way from being a testable title. *Star Castle* was a hit title for Cinematronics, but primarily because of the ingenuity and development design skills

of Scott Boden, the programmer of the game as released.

Video Game Literacy

Video game literacy is the ability to decode, understand, and create meanings through video games, and it also includes the learning experiences that result from digital play. The notion of video game literacy suggests that the video game is a medium distinct enough to have its own characteristic form of literacy. It also implies that players have to learn a new set of practices to access and communicate knowledge in the medium in which it is generated and transmitted, in this case, video games.

Throughout their history, humans have developed different technologies that help them think and acquire knowledge in different ways. The extensive influence technology exerts on human cognition can be seen throughout the major epistemological and technological revolutions in human history: the transition from orality

to literacy, a central topic researched by Walter Ong and Eric Havelock, and the advent of electronic media, followed by the rise of the digital technologies, studied by Marshall McLuhan, Lev Manovich, and Katherine Hayles. The introduction of literacy signaled a profound shift in thought processes and the development of new cognitive abilities. Ong (2002) argues that the transition from orality to literacy, an intricate and lengthy process, enabled a change in human cognition that allowed the creation of science and rational discourse, for written texts prompted the development of analytical thought and rational discussion.

The advent of electronic and new media caused a paradigm shift in the way humans think and transmit ideas, changing their conceptions of knowledge and introducing a vast range of new artifacts, such as film or radio, which helped them learn and interact with the world in novel ways. The computer proved to be the most powerful artifact of the latest technological and epistemological revolution, for it became an essential tool to access and transmit knowledge, and it brought about the development of new cognitive abilities, generally known as *digital literacy*. Video games played a crucial role in the development of this digital literacy, as they were among the first applications that allowed computers to be used in creative, original ways. Even in the early days of video games, researchers such as Alan Kay saw the huge potential of this medium to generate and communicate ideas and knowledge, and video games gradually introduced their own distinctive form of literacy.

Kay was the head of Atari's research center at the beginning of the 1980s, and was among the first to announce the

emergence of an entirely new, innovative medium that would be fundamentally different from all previous media, for it would offer new ways to represent, communicate, and animate thoughts, dreams, and fantasies through compelling worlds, images, and sounds. He suggested that video games were “a dynamic medium for creative thought” (Rheingold 1985), a thought-provoking activity that would stimulate players’ minds in playful digital environments. He worked toward the development of grand interactive experiences that would allow players to explore digital worlds and be the main characters in their own epic adventures. Video games were on their way to becoming much more than a novel application of newly developed computing power.

Video games can be studied as participatory experiences that allow players to learn through simulations, where different scenarios can be safely explored. James Paul Gee, Kurt Squire, and José P. Zagal have done extensive research on how digital environments offer learning experiences based on discovery activities, immediate response to players’ actions, and significant knowledge applied in a meaningful context. Video games allow players to thoroughly analyze a problem or an obstacle and immediately test their strategies to overcome these difficulties in a virtual world that provides instant feedback. Therefore, players have to constantly refine their approaches using the information provided by the digital environment.

James Paul Gee states that video games provide simulations that allow the development of situated understanding. Video games offer learning experiences based

on discovery activities, immediate response to players’ actions, and significant knowledge applied in a meaningful context. Gee proposes a model called the Probe, Hypothesize, Reprobe, Rethink cycle (Gee 2003, 90) to exemplify how players interact with digital environments. First, players probe and explore the virtual world of the video game, which involves looking around the map and clicking on the different parts of the environment. They then encounter a problematic situation. After careful reflection, they formulate a hypothesis about what actions or objects might be used to solve this problem. Then, they carry out strategies to overcome obstacles and complete objectives. They reprobe the digital world and test their hypotheses to see the effects they get. Players analyze feedback given by the digital game, which can either be a successful endeavor or a complete failure. They adapt their hypotheses with the information provided by the game, and they rethink the steps needed to overcome obstacles. This model is remarkably similar to the way scientists approach problems using the scientific method (Morris et al. 2013).

Kurt Squire defines *video game literacy* as “developing expertise in designing rewarding experiences for oneself within a gameworld (particularly within the game’s semiotic and rule systems)” (Squire 2008, 643–644). Different meanings are created and analyzed through the activity of digital play. Squire analyzes the different dimensions of games to understand how they foster literacy. Video games are spaces for action, where players have agency in unfolding events in the game and changing the symbols and representations within the game

world. Therefore, video games are dynamic systems that respond to players' actions. Games are a performing act, where players are actively engaged not only in the production of meanings but also in the execution of actions in these digital environments. Knowing and doing are two stages of learning that are closely intertwined in the activity of digital play. Consequently, video games foster a functional epistemology, where players learn by doing, through performance (Squire 2008). Players go through recursive cycles of perception and action, thinking and doing, within game worlds.

José P. Zagal explores how players critically engage with video games. He uses the term *ludoliteracy* to describe the particular type of literacy that arises from playing games. Zagal defines *ludoliteracy* as the ability to play games, the ability to understand meanings with respect to games, and the ability to make games (Zagal 2010, 23). Playing games is the first step in this kind of literacy, as learning to read and write would be in traditional literacy. Second, players analyze and think critically about the games they play. Zagal considers that the understanding of games is the "ability to explain, discuss, describe, frame, situate, interpret, and/or position games: (1) in the context of human culture (games as a cultural artifacts), (2) in the context of other games (comparing games to other games, genres), (3) in the context of the technological platform on which they are executed, and (4) by deconstructing them and understanding their components, how they interact, and how they facilitate certain experiences in players" (Zagal 2010, 24). Each one of these contexts explores the different facets of video

game analysis that will provide a thorough understanding of the gaming experience, which, according to Zagal, culminates in players contributing with their own video games.

Video games are valuable tools for generating knowledge because they enhance players' cognitive abilities through virtual worlds where they can enact different roles and actively experience different situations and problems, not just imagine what being in a particular situation would be like. Players exercise problem-solving skills and abstract thinking through simulations and ongoing participation. To play any video game is a cognitive exercise that ineluctably influences the way players think and learn.

Video Game Movies

Over the years, video game movies have been met with mixed reception from critics and fans of the franchises. These adaptations often receive a lukewarm reception before they have even been released. However, some video game movies have exceeded initial expectations with blockbuster budgets and A-list casts, such as *Lara Croft: Tomb Raider* (2001), the first of two movies starring Angelina Jolie as Lara Croft. Even video games themselves, mostly produced by triple-A studios, have become increasingly more reliant on filmic special effects, cinematography, and all-star casts.

However, big budgets and high-profile celebrities do not always result in successful movie adaptations of video games. Success, by Hollywood standards, is often measured by box office take as well as critical response. *Lara Croft: Tomb Raider* (2001), for example, had a budget of \$94 million and a box office take of \$274.7 million and was seen as a relative success. Whereas *Silent Hill: Revelation* (2012), starring Kit Harington, had a budget of \$20 million and generated \$56 million at the box office. Both received mixed reviews, but, fiscally, one was more successful than the other.

This is not to say that all video game movies have been a commercial failure. Even poorly reviewed films such as *Street Fighter* (1994) and *Pokémon the First Movie* (1999) made their production budgets back at the box office several times over. *Warcraft* (2016) is currently the highest-earning video game movie, with box office earnings of \$439 million, yet analysts believe it could still lose money based on the large production and

marketing budget. Short films have also had some degree of success in the field of video game adaptations. Without the pressures of needing to be a box office hit, short films can be produced by passionate amateurs who stay closer to the spirit of the game. The 2018 short film for *Papers, Please* (2013) was praised for its authenticity to the game and has overwhelmingly positive reviews. The game's creator, Lucas Pope, not only agreed to the making of the short film but also shared his approval of the final version. Some unofficial short video game movies have also been produced by dedicated fans, with varying degrees of quality and success. *Uncharted: Live Action Fan Film* (2018) is one such example of a high-quality fan film, starring Nathan Fillion as Nathan Drake, that was widely praised for its authenticity and closeness to the source material.

Researchers have highlighted a multitude of reasons for the variance of quality in movie adaptations of video games. For one, these movies are being marketed to and received by split audiences: those who have played the game, and those who have not. This split audience will likely also contain fans of particular genres, bringing other conventional expectations to the movie. Fans of the video game will scrutinize the authenticity of the details and how the video game is represented in film, whereas the general moviegoer will critique it as a successful narrative rather than as a remediation of a video game. They may recognize elements of the movie that are linked to the video game, but this will not necessarily be of importance to their enjoyment. For fans, it is the representation of the game world, rather than the core narrative, that matters when the

game world is extended. When a movie adaptation misses the mark, it alienates the video game fanbase, resulting in the movie not succeeding as expected.

Additionally, some genres are more readily ported over to the silver screen. Popular survival horror game franchises *Silent Hill* (2006) and *Resident Evil* (2002) have been made into movies, with relative success. Horror games remediate conventions of the horror film genre through mechanics to simulate the same fear and anxiety induced in audiences watching a typical horror film. Here, expectations of the genre are met, and tropes are replicated. Therefore, remediating horror games into films works well and achieves the desired style without running into issues that other productions face.

A key element of horror games is the removal of agency. One of the main discrepancies with adapting a game to a movie is situating the player into the position of audience, thus removing his or her control over the game world. As horror games have moments where player agency is removed, and this adheres to the conventions of the horror genre, it does not produce a jarring outcome but rather a harmonious blend of the two media.

Some adaptations have deviated entirely from the source material, whereas others adhere closely to the traits of the video game—sometimes too closely. *Super Mario Bros.* (1993) is considered to be the first official video game movie adaptation. Starring Bob Hoskins and John Leguizamo as the titular Mario brothers, the movie stepped away from the 8-bit style and narrative of the classic Mario games and instead used special effects and live action. While the visual effects

were impressive, the movie only drew \$20.9 million at the box office, despite a \$48 million budget. Similarly, the *Resident Evil* film series contains a character called Alice (played by Milla Jovovich) who was created specifically for the movie adaptation. After the first *Resident Evil* (2002) film, the following installments are in no way linked to the subsequent narrative in later game releases, including titles such as *Resident Evil: Apocalypse* (2004) and *Resident Evil: Retribution* (2012). Conversely, *DOOM* (2005) uses a first-person perspective sequence in an attempt to emulate the first-person shooter (FPS) camera found in the *DOOM* series. The segment in question only lasts five minutes and sees the camera “enter” Sgt. John Grimm’s view as he goes on a shooting frenzy, directly translating the typical player view to the cinema screen.

A notorious individual attached to video game movies is the now retired director Uwe Boll. Boll is most known for directing, and often also financing, movies loosely based on video games. In *The Name of the King: A Dungeon Siege Tale* (2007) was Boll’s most expensive production at \$60 million. Unfortunately, it was not received well critically and only generated \$13.1 million at the box office. This became a trend with Boll’s later video game movies, including *Alone in the Dark* (2005), *Postal* (2007), and *Far Cry* (2008).

Alongside adaptations are movies with video games as the focal point of the story, such as in *Tron* (1982). In *The Last Starfighter* (1984), Alex is the top scorer on the *Starfighter* arcade game. Upon discovering this, the creator of the game meets and abducts Alex, enlisting him into an intergalactic war, identical to that of the arcade game. This retro

arcade nostalgia was reignited in *Pixels* (2015). Aliens receive video game feeds and interpret them as declarations of war; they then invade Earth in the form of classic arcade characters, such as Pac-Man. To save the world, the U.S. Army enlists top-ranking arcade players. More recently, *Ready Player One* (2018) combined a large number of IPs (intellectual properties) from popular video games, such as *Overwatch* (2016) and *World of Warcraft* (2004), as part of the OASIS—a virtual world where individuals can do anything and everything. The film follows a great quest to find three keys embedded in the creator’s games and riddles to become the sole owner of the program and, as a result, extremely wealthy.

Some video game developers have created their own film studios. Square (now Square Enix) founded Square Pictures in 1997, intending for it to aid the company in merging CGI from film into its games. In 2001, Square Pictures released *Final Fantasy: The Spirits Within*, which had a production budget of \$137 million and earned a box office take of \$85.1 million. The reviews were negative, as fans felt the movie departed from what was near and dear to the franchise, and the movie itself did not deliver an action-packed experience but rather a more experimental and visual one. Square Pictures is now a subsidiary of Square Enix.

Current movie distribution methods such as streaming services, instead of DVD/Blu-Ray sales, have aided the success of more recent video game movie releases. *Tomb Raider* (2018) stars Alicia Vikander as Lara Croft in a new origin story based on the rebooted game franchise from Square Enix. The subject of mixed reviews, with an estimated budget

of \$106 million and a box office take of \$274.7 million, *Tomb Raider* had the distinct advantage of making profits by selling to streaming services such as Netflix and HBO, unlike previous video game movies.

As of early 2019, there are currently as many as forty video game movies currently stated to be in production. However, video game movies are notorious for getting stuck in “production hell,” where they are confirmed to be in production but are unable to be made for many years. Video game movies may never be received with open arms if the audience’s expectations are divided from the start, but there is a clear trend toward their performing better than they used to at box office. For video game fans, they can provide more of the world they love, and for moviegoers, they provide an awe-inspiring spectacle experience without having to hold the controller.

Video Game Museums

Video game museums are a global phenomenon that reflect society’s growing interest in the history and entertainment of classic video games and in nostalgia in general. While some video game preservation efforts have come and gone in recent decades, their net numbers continue to grow. These museums prove enchanting to diverse audiences while also preserving history and conducting new and ever-expanding research in this important field.

While classic arcade museums and exhibitions date back at least to the 1930s (then celebrating older machines from the rise of the coin-operated floor model amusement machine in the 1880s), video game museum efforts began in the 1990s. The growth of these efforts has accelerated. Over two-thirds of the museums listed here were established after 2010, with the majority of them created between 2014 and 2019. Of the museums

A video game exhibition at the Musee des Civilisations in Quebec City, Quebec, Canada. (Martial Genest/Dreamstime.com)

established earlier, most have experienced the bulk of their development and video game accomplishments during this same decade.

Although most museums were started by a single person or a group of friends, many have begun successfully evolving down the path of developing a wider breadth of community support. They range from spaces barely over one thousand square feet at the back of retail store in Australia, to large, financially well-endowed institutions such as the Strong Museum of Play. Some have received extensive governmental funding, especially in Europe, while others have received none. At least three have raised funds on crowdfunding sites. Some of these museums are solely focused on video games in general or in specific subsets such as console gaming. Others see their video game efforts as subsets of larger fields of interest, such as computing, play,

or pop culture. One area in which they vary the most visibly is in their respective focuses on interactive play versus traditional “Don’t Touch” offerings. Some primarily present extensive historical displays and research programs, and a few are not much more than play-oriented retro arcades with “museum” in their name. Most offer some combination of both.

The German Computerspielemuseum Berlin (<http://computerspielemuseum.de/>) began as a permanent exhibit from 1997 to 2000. It then became an online only museum until 2011, at which time it reopened a physical presence with the help of government funding. It features highly visited curated exhibits and holds one of the largest collections of entertainment software, hardware, and technical hardware in Europe.

Nagasaki, Japan, brings us the Game Museum at the Huis Ten Bosch theme park. Like many of these museums, it

balances play opportunities with exhibits. Numerous cleanly designed static displays contain console machines from the Magnavox Odyssey to today's releases. Surrounding these exhibits are numerous playable coin-operated machines and other games interspersed with roped-off arcade machines dating back to *Computer Space* (1971). It is also one of multiple Japanese locations to feature *Space Invaders Gigamax*, a video game for twenty simultaneous players with a screen 174 feet (53 meters) long and 36 feet (11 meters) high. It opened in 2014 (<http://english.huistenbosch.co.jp>).

The Museum of Soviet Arcade Machines is a private, historical arcade museum with interactive collections of video game and electromechanical game machines made from the mid to late 1970s up through the fall of the Soviet Union in 1992. With the breakup of the USSR, domestic coin-op video manufacturing found itself without subsidy nor the ability to compete commercially and quickly ceased to exist. While some of these Soviet coin-operated video games are local inspirations, a good number were copies (sometimes exact) of American arcade video games made circa 1975. All have local charm, many have military and industrial manufacturing lineage, and some have historically unique features, such as nixie tube scoring displays. All their machines are playable, and all are accompanied by informational signage. The Museum of Soviet Arcade Machines was founded in Moscow, Russia, in 2007, and a St. Petersburg branch was added in 2013 (<http://www.15kop.ru/en/>).

In Los Angeles, California, the Museum of the Game (MOG) is the fruition of multiple game enthusiast efforts

that began in the 1980s. Its live entertainment and exhibition Arcadia branch opened in 1982 in the United Kingdom and was acquired and relocated to the United States in 2003. Arcadia presents visitor-playable and nonplayable arcade, console, and computer video game history. These exhibits often focus on how the evolution of mechanical and electromechanical games dating back to the 1880s led to and inspired the video games of today. Additionally, the MOG hosts several substantial community-initiated resources with its origins on 1980s message forums and the CompuServe online service: an online game encyclopedia (renamed the Killer List of Videogames [KLOV] in 1991 and taken over in 2000) and a coin-op game census project (finally named the Vintage Arcade Preservation Society [VAPS] in 1990 and taken over in 2006). Several hundred thousand pages of PDFs and other online reference material started being added in 2008, and physical on-site library services began in 2009 (<https://www.arcade-museum.com/>).

Enthusiasts in England, the Netherlands, and the United States have each independently set up a National Videogame Museum. The National Videogame Museum, which opened in 2015 and relocated in 2018 to Sheffield, England, presents three floors of playable games and rentable space for birthday parties and other events. It specifically strives to introduce young people to video game design and development (<https://www.thenvm.org/>). The Nationaal Videogame Museum, founded circa 2017, in Zoetermeer, the Netherlands, is centered on the entertainment side of game museums, with a classic arcade offering numerous playable coin-operated video games as

well as a few cabinets and displays of handheld, console, and computer game technology (<https://www.nationaalvideogamemuseum.nl/>). The suburbs of Dallas, Texas, provide the location of the National Video Game Museum in the United States. Its primary focus is on extensive historical displays of console and handheld video game history, with a supporting room offering playable retro coin-operated machines. Temporary shows and exhibits began circa 1999. There was a Kickstarter campaign in 2011, and it opened in 2014 (<http://nvmusa.org/>).

Just outside the city center in Sydney, Australia, is the Retro Video Game Museum, a free permanent and static historical display area at the back of the back of the Gamesmen, a video game retailer founded in 1982. The small space holds multiple cases of retro console game history and two life-size character statues (<https://www.gamesmen.com.au/>).

The Strong Museum of Play in Rochester, New York, is focused on numerous areas of “play.” Its extensive, professionally produced, and highly visited exhibits are balanced with ever-growing and well-funded archiving, preservation, and academic efforts. The Strong is particularly active in the acquisition of industrial libraries and related holdings from video game companies and individual designers. The Strong’s video game activities occur under a variety of brands, including the International Center for the History of Electronic Games (ICHEG) and the World Video Game Hall of Fame. The Strong was founded in 1969 and opened in 1982. It was reoriented from a focus on regional history to a “play” theme that included video games in 2006 (<https://www.museumofplay.org/>).

The Video Game Museum of Rome features exhibits of approximately five hundred items and one hundred explanatory panels. Most of this is focused on console history, although there is some coverage of coin-operated machines and modern-day virtual reality (VR) technology. Its *E.T.: The Extraterrestrial* (1982) exhibit on items recovered from the excavation of the Atari video game burial in Alamogordo, New Mexico, is particularly memorable. The museum was established in 2012 (<http://www.vigamus.com/>).

ADDITIONAL MUSEUM PROJECTS

Australia: The Australian Centre for the Moving Image (ACMI) in Melbourne is Australia’s national museum of film, video games, digital culture, and art. During the 2015–16 fiscal year, 1.45 million people visited the ACMI. In May 2019, the ACMI closed to the public to begin a \$40 million redevelopment, with a scheduled reopening in mid-2020 (established 2002, <https://www.acmi.net.au/>).

Australia: The Nostalgia Box in Perth, Australia, is a private interactive museum of console video game history (opened 2015, <https://thenostalgiaibox.com.au/>).

Estonia: The LVLUP! Interactive Video-game Museum is a small museum with both exhibit cabinets and playable games. It can be exclusively rented out (founded 2018, <http://lvlup.ee/>).

Finland: The Finnish Museum of Games in Tampere, Finland, is uniquely dedicated to the history of Finnish games. After starting with a crowdfunding campaign, it received over one hundred thousand visitors in the first six

months of its opening in 2017 (founded 2017, <http://vapriikki.fi/en/pelimuseo/>)

Germany: The Binarium in Dortmund, Germany, focuses on all areas of German “digital culture.” This includes video game consoles, handheld games, electronic toys, calculators, and home computers (founded 2011, opened 2016, <https://binarium.de/en/start>).

Portugal: The Nostalgica Museum of Videogames and Technology has over three hundred computers, consoles, and gadgets, including video games as well as other technology from the 1970s through the present (<https://nostalgica.pt/>).

South Korea: The Nexon Computer Museum on Jeju Island combines exhibits with playable console machines. One of the key pieces in its collection is an original Apple I computer, which it purchased at a Sotheby’s auction in 2012 for \$374,500 (opened 2013, <https://nexoncomputer museum.org/>).

Ukraine: The Software and Computer Museum displays machines that range from the Magnavox Odyssey to the Apple II GS (founded circa 2017, <https://snmuseum.org/>).

United States, California: The Digital Game Museum in Silicon Valley develops special exhibits for enthusiast shows and exhibitions. It is currently working to raise funds for its own display space (efforts began circa 2009, <https://www.digitalgamemuseum.org/>).

United States, California: The Museum of Art and Digital Entertainment (MADE) in Oakland has a mission to collect, curate, and present video games (primarily console, computer, and handheld games) and game art (established circa

2010, Kickstarter campaign and opening 2011, <https://themade.org/>).

United States, New Hampshire: The American Classic Arcade Museum, located within the Funspot family entertainment center since 1998, features more than 250 vintage video game and pinball machines available for play (incorporated as a nonprofit organization in 2002, <https://www.classicarcademuseum.org/>)

United States, Washington State: The Museum of Pop Culture (MoPOP) in Seattle is a well-supported museum founded by Microsoft cofounder Paul Allen, in a building designed by famed architect Frank O. Gehry. It features exhibits covering multiple areas of pop culture, including a video game exhibit entitled the *Indie Game Revolution*. MoPOP evolved from efforts dating to 1996 and 2004, and it was rebranded in 2016 with a mission that specifically included video games (<https://www.mopop.org/>).

Globally: Several museums, including the Smithsonian American Art Museum, have hosted their own temporary exhibits, and many others have hosted traveling video game exhibits. These traveling exhibits include *Game On*, which has been seen by over two million people in over twenty countries between 2002 and 2019, and *Videotopia*, which appeared in thirteen museums and science centers across the United States from 1996 through 2011.

Video Game Novels

The novel is a genre of literature, typically a printed, “long fictional prose narrative,” “representing character and action with some degree of realism and complexity” (OED). Often distinguished from the epic, “a finished, [closed], generic form” transferring representation “to an absolute past of national beginnings and peak times,” the modern novel form (early eighteenth century onward) is open, unfinished, and expresses the author’s contemporary reality (Bakhtin 2008, 15; cf. Lukács 1971; cf. Watt 1964). Indeed, representing reality, literary critic Ian Watt proposes, is the novel’s “primary convention” (32). This convention, or “formal realism,” connotes the novel’s aspiration to provide “a full and authentic report of human experience . . . [that] satisf[ies] its reader with such details of the story as the Individuality of the actors concerned [and] the particulars of the times and places of their actions” (32). Because the novel seeks to represent the present, both its form and notion of *realism* are mutable, open, and actualized as history unfolds. As Russian philosopher,

Mikhail Bakhtin, writes, the novel is “plasticity itself” (2008, 39), a “zone of direct contact with developing reality” (2008, 3) “that continues to develop, that is as yet uncompleted.” The novel is forever novel. It forms and reforms across and within respective milieus.

It follows, therefore, that late twentieth-century to early twenty-first-century novels express so-called digital culture in both form and construction of “reality.” The *video game novel*, in its appropriation of the formal attributes, tropes, experiences, and culture of digital games, is one such expression. Indeed, the video game novel exemplifies what media scholar Henry Jenkins refers to as contemporary “convergence culture” in which, due to various cultural, technological, and economic factors, existing forms and genres frequently combine to make new ones (Jenkins 2006).

This entry provides a taxonomy of non-mutually exclusive, subgeneric tendencies under the broad designation *video game novel*—the ludic novel, the gamer novel, and video game novelization—with attention paid to respective precursors. To distinguish from discourse on electronic literature and games, *novel* here denotes “long fictional prose narrative[s]” primarily appearing in print.

LUDIC NOVELS

Referred to as both “ludic” (Kuehl 1986; Detweiler 1976; Condis 2016) and “gamic” (Jupin 2015) fiction, ludic novels employ formal attributes associated with games—play, nonlinearity, interactivity, rules, and boundaries—with varying degrees of intensity (cf. Ensslin 2014, 27–31). As ergodic texts, traversing the

ludic novel entails “non-trivial effort” (Aarseth 1997, 1); to comprehend its storyworld, the ludic novel “require[s] game-playing and puzzle-solving of readers” (Condis 2016, 2). In short, not only does the ludic video game novel concern video games, but it is also, itself, a game. Examples of this “transfection of gamic conventions” (Galloway 2006, 62) into print novels about video games include the “Easter egg hunt” embedded in Ernest Cline’s *Ready Player One* (2011), the fragmentary clues readers must piece together throughout Neal Stephenson’s *Reamde* (2011), Cory Doctorow’s downloadable and remixable *For the Win* (2010), and the cheat-code-esque “crib sheet” accompanying Charles Stross’s first-person-shooter-style *Halt-ing State* (2007) (Jupin 2015, 76). Besides early text-based adventure video games (such as *Colossal Cave Adventure* [1976]), nonprint precursors for playful, interactive storytelling range from tabletop role-playing games (RPGs) like *Dungeons and Dragons* (1974) to oral, round-robin storytelling. Playful print antecedents requiring forms of ergodic traversal include biblical glosses (Ensslin 2014, 11), Dadaist “cut-ups,” Doris Webster and Mary Alden Hopkins’s *Consider the Consequences!* (1930), Jorge Luis Borges’s *The Garden of Forking Paths* (1941), Alan George’s *Treasure Hunt* (1945), Robe-Grillet’s novels, *TutorText* interactive textbooks inspired by B. F. Skinner (1958–72), Vladimir Nabokov’s *Pale Fire* (1962), B. S. Johnson’s *The Unfortunates* (1969), postmodern fiction (cf. Edwards 1998), and gamebooks (cf. Katz n.d.) popularized by the *Choose Your Own Adventure* franchise (1979–98).

GAMER NOVELS

There cannot be a video game novel without video games. Where the ludic novel provides a formal expression of games in general, the gamer novel invokes the realities of video game culture as content: “the fiction in which particular games are portrayed and indeed usually form the foundation of plot, characterization, or imagery” (Detweiler 1976, 48). Analogue precursors include sport-oriented novels such as A. G. Macdonell’s *England, Their England* (1933); Robert Coover’s *The Universal Baseball Association* (1968); Michael Murphy’s *Golf in the Kingdom* (1971); and Haruki Murakami’s *Pinball, 1973* (1980). With its unlikely gamer heroes and focus on advanced technology, however, critics typically draw connections to speculative cyberpunk fiction (cf. Condis 2016; cf. Sterling 2003 for “cyberpunk”) such as William Gibson’s *Neuromancer* (1984), Orson Scott Card’s *Ender’s Game* (1985), Neal Stephenson’s *Snow Crash* (1992), and Tad Williams’s *Otherland* tetralogy (1996–2001).

Like cyberpunk fiction, the gamer novel might tell stories within video game/virtual reality (VR) worlds or about video game playing, but, most significantly, it mobilizes a field of referents shared by readers embedded in gamer culture. Examples include Terry Pratchett’s *Only You Can Save Mankind* (1992), D. B. Weiss’s *Lucky Wander Boy* (2003), Dennis Cooper’s *God Jr.* (2005), Ernest Cline’s *Ready Player One* (2011) and *Armada* (2015), Christopher John Farley’s *Game World* (2014), Cory Doctorow and Jen Wang’s graphic novel *In Real Life* (2014), Keith Stuart’s *A Boy Made of Blocks*, Marie Lu’s *Warcross* series

(2017–), Douglas Lain’s *Bash Bash Revolution* (2018), and Jason Segel and Kirsten Miller’s *Otherworld* (2018). Representation of video game development is also a significant trend. Often semiautobiographical, video game design novels are typically focalized through people involved in the game industry. Examples include Douglas Coupland’s *JPod* (2006) and Austin Grossman’s *You* (2013).

VIDEO GAME NOVELIZATIONS

The video game novelization is predicated on a long history of transmedial adaptation (cf. Hutcheon 2013, Sanders 2016). Sometimes known as *tie-ins*, these derivative novels adapt the story or storyworld—heterocosm (Hutcheon 2013, xxiv)—created for a published, usually popular, video game. While other video game novel types listed here make reference to or take on the tropes of specific video games, these books attempt a direct transposition of a video game title into a novel. Notable examples of adapted franchises include *Assassin’s Creed*, *Diablo*, *Halo*, *Myst*, *Resident Evil*, *StarCraft*, and *World of Warcraft*. Typically, companies contact and invite authors to write the novelization. According to the International Association for Media Tie-In Writers, companies require more than a “word-for-word regurgitation of their game” and encourage authors to develop characters, parallel stories, and subplots—“[t]he key is to tell the story that never made it to the screen” (Dietz n.d.).

In sum, the video game novel might tell stories within video game worlds, about video game playing, or about video game making; employ the tropes of video games for content; or take on the formal

components of games. In this way, the conventional “realism” of the modern novel now firmly enfolds our virtual, pixelated lives.

Video Game Studies

Video game studies is multidisciplinary, combining elements from many fields, although the majority of them come from media studies and traditional game studies. Although game studies in general looks at play and games in the broadest sense of the term, video games studies looks more narrowly at video games and must take video game technology and conventions into account.

Because video games are also an industry, a technology, an art, a form of communication, an educational tool, and a social tool, video game studies tries to encompass all these things and examine how they are related. The academic study of video games began slowly, arising first in the 1970s as the subject of discussion for homebrew electronics hobbyists who built their own computers and programmed their own games. During the 1980s, video game designers began writing about their ideas and work and occasionally theorizing about video games, perhaps most notably in Chris Crawford's *The Art of Computer Game Design* (1982). The 1980s and 1990s also saw the rise of academic interest in video games from a psychological perspective, particularly in the areas of aggression, socialization, and other health issues. In the late 1990s and early 2000s, video games began to be addressed from the perspective of media studies and were compared with other media, such as film, television, and interactive fiction or hyperfiction. During this time, video game studies concentrated on demonstrating the unique qualities of video games as media objects and argued that a new field of study was needed to take these aspects into account. Only once the field became

more established late in the first decade of the twenty-first century could books and writings take for granted that video game studies had become an accepted area of study unto itself. This same decade also saw the increase of conference papers, online journals such as *Game Studies*, and, finally, entire conferences devoted to video game studies. Today, video game studies has become one of the fastest-growing branches of media studies.

Because *studies* is a broad term, *video game studies* includes not only theory but history as well. Video game history began with historical summaries found in magazines, such as the multipart “Electronic Games: Space-Age Leisure Activity” by Jerry and Eric Eimbinder, which began in the October 1980 issue of *Popular Electronics*, and later in early books such as George Sullivan’s *Screen Play: The Story of Video Games* (1983), which was intended for a juvenile audience. Interest in video game history picked up during the 1990s, with Leonard Herman’s *Phoenix: The Fall & Rise of Videogames* (1994), being the first history of video games written for an adult audience, and in the next two decades, a number of books on video game history would appear, from books on individual companies to more general histories, written from popular, journalistic, and academic perspectives, and a variety of websites on video game history exist as well.

Video game studies also brings video game history and theory together in the examination of how video game designs, genres, and conventions grew over time and how these were affected by such things as programming languages, available technology, business practices, popular culture and cultural norms, and

exchanges and influences from other media and media forms, including film, television, computers, role-playing games (RPGs), board games, sports, and puzzles. The form, content, and context of video games and how they are related are also subjects of study.

In addition to being a branch of media studies, video game studies has renewed interest in traditional game studies, which has provided concepts and tools useful to the study of video games. In this perspective, it is significant to establish exactly what a game is (see Game, Definition of) to understand games in regard to criticism, analysis, and design. Other overlapping areas and issues shared by video game studies and traditional game studies include the study of play and players, game structures, game aesthetics, and game culture.

Although video game studies is new enough that various “schools” have not yet coalesced, some have suggested that early on a debate existed between narratologists, who argue that video games should be analyzed as narrative forms, and ludologists, who argue that games should be analyzed from the perspective of game studies; yet, in the end, these two positions were not seen as being irreconcilable but rather complementary aspects. Today, video game studies is incorporating an ever-widening set of approaches, using analytical tools from a diverse range of fields, including art and aesthetics, artificial intelligence (AI), business and industry, communication and social science, media studies, game studies, computer graphics and programming, education, philosophy, semiotics, psychology, human-computer interaction, and more. Each of these fields has its own discussions of the capabilities and uses of

today's video games as well as what they could become in the future. For example, social scientists have studied the communal aspects of massively multiplayer online role-playing games (MMORPGs); in the field of psychology, much discussion has occurred regarding the connection between video games and aggressive behavior; and in the field of education, video games are studied as educational tools. Video games studies can therefore be seen as a nexus where all these questions and concerns intersect and interact.

Video Games and Literature

Throughout cultural history, we can observe how different media influence and transform each other. The intermedial exchange is not the exception but the rule. Traditionally, the relationship between literature and play is particularly close, as Johan Huizinga noted in his study *Homo Ludens: A Study of the Play-Element in Culture* (1938). For video games, two types of intermedial influence can be distinguished: first, the historical impact of literature on the emergence of digital games as a narrative medium and, second, the current interrelations between literature and games.

In the early twentieth century, several decades before the emergence of video games, aesthetic desires for new multilinear and interactive forms of narration

became apparent. The literary avant-gardes reacted to them first. In the 1920s, the Dadaists and the Surrealists started to experiment with ludic approaches in writing literary texts under the constraints of gamelike rules. Tristan Tzara, for example, tried to create poems by pulling words out of a hat, and André Breton and fellow surrealists experimented with several methods of automatic writing. In 1941, Jorge Luis Borges's short story "The Garden of Forking Paths" suggested the concept of branching text as it was later developed in the form of text adventures and hypertext novels. In 1961, Marc Saporta published *Composition No. 1*, 150 unnumbered pages delivered in a box to be read in arbitrary order, and Raymond Queneau published *Hundred Thousand Billion Poems*, a specially designed book of ten sonnets whose lines could be randomly combined. Two years later, Julio Cortázar's novel *Hopscotch* invited its readers to follow different reading paths. In 1967, Queneau published the multiple-choice short story "A Story as You Like It," which anticipated the genre of adventure books or gamebooks that would become popular about a decade later.

These examples and many others of the 1950s and 1960s document how literary experiments tested narrative forms and effects in analog media that video games would later realize in the new digital medium of software. Common to these literary experiments was that they attempted to overcome the linearity of storytelling and to reduce the dominant role of the author in favor of the recipients' agency.

In the 1970s, digital games started to catch up with the experiments of the literary avant-gardes when text-based

adventure games, first on university mainframes and later on personal computers, allowed players to navigate branching plots by answering text prompts. The prototypical game of this emerging genre was to become the *Colossal Cave Adventure* (1976). Originally based on the real-world experience of spelunking, several revisions added elements of the then new analog roleplaying game *Dungeons & Dragons* (published in 1974) and of literary fantasy in the Tolkien tradition. Other influential text adventures were *Zork* (1977–82) and *Mystery House* (1981) and two literary adaptations: the text adventure versions of Douglas Adams's novel *The Hitchhiker's Guide to the Galaxy* (1983) and Ray Bradbury's *Fahrenheit 451* (1986).

With text adventures, games started to develop their very own modus of narration. The genre proved that games, while using the model of literature, could overcome more than some of the limitations of storytelling in analog media and provide a unique narrative experience. Whoever typed their way through these "webbed" text passages was introduced to new experiences of decision making and independence and of immersion and calculation. The gameplay, however, was constrained by the ability or, rather, inability of contemporary programs (the "parsers" of text adventures) to understand natural language input. A logical next step was to create multiplayer versions to replace at least parts of the interaction with the software by interaction with more "understanding" humans. At the end of the 1970s, the game *MUD* (*Multi-User Dungeon*) went online, again on a university mainframe, and gave the new genre its name. In 1981, this first MUD was connected to the ARPANET

and became the first internationally networked online game.

The development of digital storytelling following the 1970s changed the new medium of digital games. Until then, video games were purely ludic and often just procedural adaptations of analog games such as chess or table tennis. Now digital games gained the affordance of narrative expression. Using the specific abilities of digital textuality for multilinearity, text adventures and later graphic adventures enhanced storytelling far beyond the possibilities of analog literature. Most importantly, temporal linearity as it characterizes literary, as well as cinematic storytelling, is complemented with or replaced by spatial forms of narration whose temporal dimensions are realized anew with every playthrough.

Presently, the intermedia relations of literature and games are characterized by two major exchanges. First, there are direct adaptations of work: literature to games and games to literature. Hundreds of games are based on novels, short stories, poems, and theater plays. Authors whose works have been adapted range from Dante to Poe to Lewis Carroll to Kafka and from Tolkien to Tom Clancy to J. K. Rowling to Andrzej Sapkowski. An extraordinarily successful adaptation of literature is the *Witcher* trilogy, having sold more than thirty-three million copies worldwide. Even more widespread is the literary practice of adapting games or extending their storytelling through the novelization of prequels, interludes, and sequels. Several hundreds of such novels are available; for example, there are nine novels set in the *Assassin's Creed* universe and two dozen novels set in the *Halo* universe (see Video Game Novels).

Second, there are the more indirect but at the same time broader influences of

literary works on games. Genre exchange plays a particularly important role. Video games were and are profoundly affected by science fiction, fantasy, and horror literature (and movies of these genres which themselves are often based on genre literature). Many successful games of the last decade also employ literature, literary techniques, and narrative styles. Some simply integrate reading material into their worlds: the *Deus Ex* series (2000–16), for example, offers texts of many genres, from newspaper clippings to letters to cooking recipes to excerpts from a G. K. Chesterton novel, and *Skyrim* (2016) includes hundreds of books with thousands of pages. Other games make use of established literary forms and devices, such as the epistolary novel (*Dear Esther* [2010]) or the unreliable narrator (*The Stanley Parable* [2011] and *The Beginner's Guide* [2015]). The reverse case—the influence of video games on contemporary literary storytelling—is harder to assess, and research is still required.

Video Games as Collectibles

Video games, whether on disc or diskette, cartridge or CD-ROM, were once objects you could hold in your hand, you could put them on a shelf, and you could collect them. But with online portals and direct downloading, games as physical products are gradually becoming a thing of the past, which may signal an end to video games as collectibles.

THE RISE OF COLLECTIBLES AND COLLECTING

Items that people collected have been around ever since objects and materials have been used as currencies, and people have long collected books and works of art. But the idea of *collectibles*—objects that are deliberately designed to be collected or made with collecting in mind—has been around since 1875, when cigarette cards first appeared. Cigarette cards were trading cards included in packs of cigarettes, with hand-painted images of national flags, Indian chiefs, and wild animals, but the best-known cigarette cards had images of baseball players; these started the sports cards industry. The second-most expensive baseball card in the world is the Honus Wagner cigarette card, which sold for \$3.12 million in 2016. The card is very rare because Wagner was antismoking and threatened legal action if the card was released, so only a few ever made it into circulation.

Collecting became more popular during the prosperity of the Industrial Age and the early twentieth century, when merchandise and memorabilia were produced. But the rise of collectibles and collecting culture as we know it today occurred during the 1960s and 1970s.

Several factors may account for this, such as the rise of merchandising and franchising, along with the rapid cultural change of the time, which led to a greater nostalgia for the past, along with marketing done with that nostalgia in mind, such as George Lucas's 1973 film *American Graffiti*, which started the genre of the nostalgia film. Movie card collecting and other kinds of nonsport cards joined sports card collecting, and during the 1960s and onward, companies such as Topps, Fleer, and Donruss expanded out from sports into other areas, appealing to the growing fan bases of movies and television shows.

Collecting can be seen as a desire to keep the past intact, in the form of artifacts, and the later shifts from analog to digital technology brought further cultural change as well as attention to the physicality of objects. Faster cultural change leading to faster obsolescence increased some items' rarity, making them more desirable to the collector; in this way, collecting can be something like a game itself. Rarer items are more difficult to find, and collections are considered less complete without them. It should also be noted that companies selling items intended as collectibles often sold the items individually, not as complete sets, to make the completed collection a more elusive goal. The gamelike nature of collecting suggests that it may appeal to gamers and help video games become collectibles as well.

VIDEO GAMES AS COLLECTIBLES

Video games, appearing commercially in the 1970s and becoming a cultural force during the late 1970s and 1980s, grew up alongside these trends and became a part

of them as generations of console technology began replacing older systems, gradually becoming collectibles themselves. Video games began to be seen as collectibles when games were separated from the consoles that played them, with the idea of removal game cartridges. When Atari allowed the third-party production of cartridges for the Atari VCS 2600, dozens of companies came out with games for the system, many of which were produced in relatively small numbers, leading to their greater rarity in the future. Handheld game series, such as Nintendo's Game & Watch series, also encouraged buyers to start a collection. The idea of collecting changed marketing insofar as it was not the selling of a single product but a line of products to which new products were continually being added, so the buyer's goal was not just the ownership of a product but of an entire collection, seen as a whole.

As time went on, video game technology advanced, with new console generations appearing about twice a decade on average, a much faster advance than technological generations in any other areas. As games and systems quickly receded into the past, nostalgia grew in the form of retrogaming and video game collecting, both of which were aided by the World Wide Web, which made it easier for collectors to find and trade information. The decline of the video game arcade and nostalgia for its brief golden age led to game collecting groups such as the Video Arcade Preservation Society (VAPS), which began in the 1980s and today has over ten thousand members in seventy-one countries. Internet auction sites such as eBay have also helped raise the prices of rare games by casting a wider net for buyers.

Video games, and collectibles in general, are more valued the rarer they are. The Atari cartridge *Atlantis II* (1982), for example, was only offered as a reward to high-scoring players of the much more common *Atlantis* (1982) who photographed their high scores and sent them in to receive the sequel, which was never sold commercially. Today, the cartridge is valued at about \$6,000 (Lammle 2011). Other rare cartridges for the Atari VCS 2600 have sold for even higher prices; in 2012, Inspirational Video Concepts' *Red Sea Crossing* (1983) sold for \$10,400, and in 2010, Men-A-Vision's *Air Raid* (1982) sold for \$33,433 (Sharp 2019). However, the most expensive video game ever sold was a cartridge for the Nintendo Entertainment System (NES). Nintendo hosted the Nintendo World Championships in 1990, which used custom cartridges made especially for the event. Ninety were made in gray, like other Nintendo cartridges, but twenty-six more were made in gold and given away as prizes. As the rarest NES cartridge, the gold version sold for \$100,088 on eBay in 2014 (Sharp 2019).

Game cartridges are able to attain such values due to their physical nature. Downloadable games that are endlessly copyable and are not tethered to a physical container have lost their physicality and status as objects, and even though they are arguably more ephemeral and vulnerable to erasure and disappearance, one copy is enough to reproduce the game many times over and quickly reverse the declining number of copies. Physical artifacts such as cartridges were more expensive to make, but they also made piracy more difficult, which was another advantage for collectors, who would want to avoid counterfeit games.

Physical game cartridges and other media are objects that can be preserved and archived as well as displayed in museums and other exhibitions, helping to keep an interest in the medium's past. As a physical object, the game was expected to have paratextual and extratextual materials, such as the game manual, the box, and other packaging, and sometimes the additional items included in collector's editions, such as figurines, soundtracks, cloth maps, or other such items. These things often became valuable to collectors, and they were sometimes even rarer than the game cartridges themselves, as things such as packaging tend to be discarded and not saved (although this would change sometime during the 1990s or so, when people began to realize the value of such things as collectibles, and so more people began saving packaging). These items are sometimes even bought and sold separately from the game cartridges; the box for *Stadium Events* has been known to sell for as much as \$10,000 (Lammle 2011).

The physicality of video game cartridges means they can be archival objects, to be cataloged, stored, preserved, and exhibited later. Even when video games moved from cartridges to optical discs, there was still a physical container for the game, though admittedly a more vulnerable one. Just as one could take a cartridge or a disc over to a friend's house and play the game on his or her system, the physical manifestations of video games preserve them better over time, though of course the console systems need to be preserved as well. A game on a cartridge or disc can be played on any console of the right type and does not need to be stored on the console, as a downloaded game does,

taking up memory and ultimately limiting how many games can be played on a particular console.

THE FUTURE OF VIDEO GAMES AS COLLECTIBLES

Now that video games are often sold directly to consumers as downloads or data streams, many are no longer sold as data stored on physical carriers such as cartridges or discs, which means that they are far less likely to become collectibles in the future. And because they are stored directly on the hard drives of computers or consoles, they are more vulnerable to being lost or erased or simply not saved when players make room for newer games. Still, systems that use game media, such as the Nintendo Switch as well as handheld games, will allow the video game to continue as a collectible. System hardware can also become collectible, along with peripherals and other such items, but most of them will be of limited value due to the large number of systems that are normally produced. And, naturally, older video games will remain collectible, as they grow even older and rarer as time goes by.

Worth).” TheGamer, January 16, 2019. Available at <https://www.thegamer.com/console-games-rarest-ever-worth/>.

Video Games within Video Games

Some video games give players the opportunity to play analog games as part of the gameplay itself. Card games are especially popular, with different versions in different titles, such as Caravan in *Fallout: New Vegas* (2010) and traditional games of poker in *Far Cry 3* (2012). We also find other popular games, such as Liar’s Dice in *Red Dead Redemption* (2010) or billiards in *Grand Theft Auto: San Andreas* (2014) and *Grand Theft Auto IV* (2018). However, there are instances of video games where players can play video games within the video game itself. Among the earliest examples of video games within a video game are the fictional arcade games *Ship Chip Lander* and *Rubber Gut* found within the diegesis of *Cosmic Osmo: The Worlds beyond the Mackerel* (1989), which the player can actually play within the game. While some games within games are fictional, in other cases, the featured titles are influential video games of the past. This can be seen as a tribute to the video games that shaped the earlier years of the industry and paved the way for the titles to come. Other times, the video game inserts itself as another version of the main video game the player is playing.

Call of Duty: Black Ops (2010) is a first-person shooter (FPS) developed by Treyarch and released for PC, PlayStation 3 (PS3), Xbox 360, and Wii. The game follows CIA operative Alex Mason as he travels to different locations around

the globe in the 1960s, during the Cold War. Players have to get up from the chair in the main menu and walk up to a computer terminal in the background. If they type “Zork” in that terminal, they can unlock the original game. *Zork I* (1980) is among the earliest text adventure games. To explore the digital world of *Zork*, players type commands that allow them to move and interact with objects. If players type “DOA” in the same terminal, they unlock *Dead Ops Arcade*, a twin-stick top-down shooter, where the main objective is to survive for as many rounds as possible while fighting increasingly difficult waves of zombies.

Fallout 4 (2015) is a postapocalyptic action role-playing game (RPG) developed by Bethesda Game Studios and released for PC, PlayStation 4 (PS4), and Xbox One. The game takes place in the city of Boston and the surrounding area of Massachusetts. The main character, the “Sole Survivor,” explores the wasteland in search of his/her missing son while completing objectives and helping the different factions. The protagonist was in a cryogenic state in Vault 111, an underground refuge. When players explore the ruins of said Vault, they discover a video game called *Red Menace* in the recreational terminal in the cafeteria of Vault 111. In *Red Menace*, a Vault-Tec Boy has to rescue a Vault Girl from an alien-looking Chinese flag that drops bombs and barrels while the Vault-Tec Boy climbs the stairs, dodging bombs and jumping barrels thrown by the enemy; the game is reminiscent of the Nintendo arcade hit *Donkey Kong* (1981).

Catherine (2011) is a puzzle platformer adventure game developed by Atlus released for PS3 and Xbox 360. It was later released for PC by SEGA in 2019.

The game follows the story of the protagonist Vincent, who is torn between his longtime girlfriend, Katherine, and Catherine, an attractive woman he just met. The gameplay is divided between the time Vincent spends in the Stray Sheep bar with his friends or trapped in a nightmarish world where he has to climb giant staircases using the diverse properties of the cubes that make up the staircases. When Vincent is in the bar, he can play an arcade version of his own nightmares. This video game is called *Rapunzel*. It mimics the main gameplay of *Catherine*. However, the primary difference is that *Rapunzel* gives players a limited number of moves, whereas during the main stages in *Catherine*, players have a limited amount of time to clear the stages. *Rapunzel* has 128 levels, or 64 for each mode, and the player is allowed to play three times per night. Every time Vincent beats one of the modes, he gets achievements and access to extra stages.

Video games appearing within the diegesis of other video games demonstrate how far the medium has come and a nostalgic self-reflexive tendency for the medium's own history. Such games are also an interesting way to remind players that they are playing a game, simultaneously indicating how far the medium has advanced, and some games within games become a form of self-critique that calls attention to the nature of games themselves.

Videotopia

Videotopia was a traveling exhibit (managed by Electronics Conservancy Inc.) dedicated to the art, science, and technology of video games. It was designed and assembled by Keith Feinstein with the help of a large advisory board made of game historians and key industry figures. Since its first showing in 1996 at the Carnegie Science Center in Pittsburgh, it has been showcased in a dozen major science museums around the United States, including the Franklin Institute Science Museum in Philadelphia and the Singapore Science Center. In its complete form, it featured more than one hundred arcade machines, a variety of home console systems, interactive touchscreen kiosks, and numerous information pedestals.

At the entrance of the *Videotopia* arcade, there was a two-sided kiosk entitled “That was then . . . this is now.” On one side, an Atari VCS 2600 was connected to a CRT television, and the other side featured a more recent console. Many of the arcade games featured in the exhibit represented a technological or commercial breakthrough in the history of video games. Some of the earliest coin-operated machines (*Computer Space* [1971] and *PONG* [1972]), the first game to store graphics on a ROM chip (*Tank!* [1974]), the first to use a microprocessor (*Gun Fight* [1975]), and the first to feature

a two-way scrolling playfield (*Football* [1978]) were on display. The full exhibit also included laserdisc games (*Dragon's Lair* [1983]) and a section on the evolution of three-dimensional graphics, including *Battlezone* (1980), *I, Robot* (1983), and *Virtua Racing* (1992). Many genre-defining blockbusters were featured: *Space Invaders* (1978), *Asteroids* (1979), *Pac-Man* (1980), *Donkey Kong* (1981), *Centipede* (1981), *Joust* (1982), *Tron* (1982), and *Gauntlet* (1985), to name just a few. The exhibit has been updated on several occasions with more recent games, such as the rhythm game *Hip Hop Mania Complete Mix* (1998). On its showing at the Mary Brogan Museum of Art and Science in Tallahassee, Florida, Microsoft's Kinect peripheral for the Microsoft Xbox 360 was installed and ready to play.

The *Videotopia* exhibit sought to introduce visitors to the technological aspects that are essential to understanding the video game experience and its evolution and to demystify the creative process of these games. The “Look Inside” section included blown-up design documents, a display that revealed the inner working of typical interfaces, and two interactive information kiosks operated by touchscreen. In this section, users could learn about the different steps of the creative process—from the initial ideation to rules design and character and story creation—and major technological components: raster displays, vector displays, transistors, microprocessors, RAM and ROM chips, and so on. Additionally, many pedestals were positioned next to specific games or groups of games to give information about the design process and gameplay mechanics or to explain the evolution of a game genre (e.g., the evolution of “slide and shoot” games

with *Galaxian* [1979], *Galaga* [1981], and *Xevious* [1983]). The pedestals also provided contextual information about what was happening in other cultural domains (such as the news, television, and movie theaters) when these games were released.

More than one hundred machines of the original collection have been bought by the Strong National Museum of Play in Rochester, where the exhibit was featured during the last half of 2009. *Videotopia* has played a significant role in bringing a comprehensive view of video game history to the museum space.

Vintage Arcade Preservation Society (VAPS)

The Vintage Arcade Preservation Society, originally known as the Video Arcade Preservation Society, or VAPS, is a leading organization and census project dedicated to the preservation of classic arcade and video games. More than ten thousand members in seventy-one countries have worked to preserve classic arcade machines and their history. Collectively, these members hold more than 130,000 classic coin-operated machines (over 6,400 different titles).

Just as the Killer List of Videogames (KLOV) started out as an informal list of

coin-operated video games distributed via online bulletin board systems (BBSs) and CompuServe during the 1980s, VAPS began as an informal list of dedicated collectors distributed on those same systems. Both the KLOV and VAPS launched websites in 1994. A key part of VAPS was, and continues to be, an extensive and constantly updated online census of surviving coin-operated machines. VAPS utilizes the official list of games from the KLOV to determine what games can be added to its census database, and VAPS members enter in each game in their game holdings.

In 2006, the leadership of VAPS was handed over to the International Arcade Museum (IAM), both of which are now part of the Museum of the Game. In 2009, VAPS's website was moved to the site of the International Arcade Museum (www.arcade-museum.com) so that functions from each site could be better integrated and to reflect the fact that many members of VAPS were members of the KLOV and used a single social and machine preservation message forum system offered by the International Arcade Museum.

As the KLOV's and IAM's online encyclopedia began to cover more and more non-video game coin-operated machines, so did VAPS. Thus, in 2010, the Video Arcade Preservation Society was renamed the Vintage Arcade Preservation Society to better reflect VAPS's expanded mission. Today, the VAPS census project has been expanded to cover machines and parts owned, for sale, and wanted. Interpretation of census data through reports and graphs are available online, and new features are added on a regular basis.

Violence

Research on violence in video games is typically explored in two ways: through “media effects” models inherited from studies of violent content in film and television and through sociocultural models arguing that video games and “violent game content” must be contextually situated within a broader culture of media and everyday violence.

In popular media, the relationship between violent action and violent video game content has been widely sensationalized through stories about violent and aggressive actions resulting from video game play. For example, the media blamed mass shootings in Columbine, Colorado, in 1999; Munich, Germany, in 2016; Parkland, Florida, in 2018; and many others on the violent video games that their perpetrators played. However, sensationalist media attempts to pinpoint a causal link between video game play, including commentary by U.S. president Donald Trump, who claimed that video games were to blame for a mass shooting (Scutti 2018), have not been substantiated by empirical research (APA Task Force on Violent Media 2015). Video games, just like other media, rely on and reproduce cultural norms with regard to violence, and first-person

shooting video games have remained popular since their inception, despite their controversial content.

Unlike other screen-based media, however, video games uniquely position their players in active roles in relation to violent behaviors in a game; players have control over considerable violent action within the game and typically must choose violent means for conflict resolution as well as seek to be successful at it. For some researchers (Anderson 2004; Anderson, Gentile, and Buckley 2007), this “active” engagement with violence (instead of merely “viewing”) increases violence-related “effects” on players, namely increased aggression. That said, whether it is the activity of the player’s engagement with violent media that *produces* either temporary or longer-term violent effects, including criminal behaviors, or that there are such effects—whether cognitive, behavioral, or affective—is no longer questioned by media effects researchers, who have consistently been able to document a causal relationship between viewing/playing with violent media content and inducing violent effects (Anderson et al. 2003; Bushman and Anderson 2009).

With respect to aggression specifically, the violent video game effects literature has successfully demonstrated that there is a causal link between playing violent video games and the inducement and reinforcement of aggressive feelings and behaviors. Work by Barlett, Anderson, and Swing (2009), in a review of violence effects in literature and video games, divides the wide range of literature available on the topic into three categories: aggressive cognition, aggressive behavior, and prosocial behavior. In the first,

studies have demonstrated that there is indeed a relationship between violent video game playing and “aggressive priming, activation of aggressive scripts and knowledge structures and a hostile attribution bias compared to non-violent video game exposure” (Barlett, Anderson, and Swing 2009, 382). Aggressive behavior has been measured using a variety of methods and tools, including observations, self-reports, standard laboratory tests, and so on, and has shown, through numerous comprehensive reviews, that violent video game exposure leads to increased violent behavior (Anderson et al. 2003; Anderson et al. 2004, 2007; Barlett, Anderson, and Swing 2009; Ferguson and Kilburn 2009). Prosocial behavior, which includes empathy and the helping or rewarding of others, has also been shown to decrease with exposure to violent video games (Bushman and Anderson 2009; Funk et al. 2004). Meta-analytic reviews of studies have continued to show that regardless of the design of the research (experimental, cross-sectional, or longitudinal), it is possible to correlate video game violence exposure to aggressive behavior, hostile affect, psychological arousal, and decreases in prosocial behavior (APA Task Force on Violent Media 2015; Anderson 2004; Anderson et al. 2010).

Partly in response to the psychological effects literature, as well as to the intense media pressure resulting from reports of violent video games leading to violent actions, the video game industry’s Entertainment Software Ratings Board (ESRB) has a rating system for violent content, similar to that of the movie industry, by which violent content is reviewed and rated. North America, Europe, Japan, Australia, the United Kingdom, and Finland have ratings

systems in place (e.g., the Pan European Game Information [PEGI] system) to make consumers aware of violent content and to indicate the age group for which the game is appropriate.

Complicating any attempt to demarcate and rate media by reference to their levels and kinds of violence, however understandable its appeal, is the very meaning of *violence*, when its referent is a programmed play mechanic. No less troubling is the real/play distinction, illustrated by Bateson's "nip" versus "bite" distinction and Johan Huizinga's "magic circle," that always inadequately seeks to demarcate "real violence" from "just playing." And not all ways of playing with "violence" are the same: the ways player agency is implicated and involved in (virtual) violent behaviors in games within the horror genre, which has more than its share of video game violence, may be positioned in opposition to (game) violence, playing not for the sake of engaging in violence but rather playing defensively, protectively, or self-protectively (Perron 2009). The appeal of such unabashedly violent games are the feelings of suspense, anticipation, dread, shock, and terror that such games are more or less ingenious at inducing in their players.

So although effects researchers are well able to show positive correlations (especially related to aggression) and to reproduce their findings, the difficulty in this approach to the question seems not to be reproducibility but deep unreliability at the level of context: what is the relationship between experimental context and aggressive behavior in the world writ large? Media scholars and socioculturalists insist that linking violent video game play to real-world dispositions,

behavioral outcomes, and antisocial actions misses the wider sociocultural context in which video games are played (Jenkins 2006; Tappan and Kita 1999). These counterarguments to psychological studies that reproduce violent effects in their research participants are not research based but instead contribute a crucially important theoretical consideration to these debates: what do we really know about the relationships between (sometimes) violent content in video games and the larger meanings both adults and children make in relation to that content?

This theoretical position views the psychological effects literature as abstracting the question from its larger situation, simplifying it, at times, beyond any usefulness in terms of individual meaning-making. The "meanings not effects" model asks the question of a wider range of distributed and dispersed, networked sociocultural actions and events. This position does not discount the psychological effects literature but rather asks how it can disambiguate simulated aggression and player excitation from the larger sociocultural complexities of everyday life, a question that has not yet, however, stimulated the research needed to persuade those for whom a compelling, if simplistic, causal model has the final word.

Violence sells in all media, and video games are no exception, although many best-selling games (such as *Pac-Man* [1980], *Super Mario Bros.* [1985], *Myst* [1993], *The Sims* [2000], and *Wii Sports* [2006]) are relatively nonviolent games. Whether and how playing violent video games over time in a context of media and cultural violence can be disambiguated from that context remains, "effects"

research notwithstanding, very much open to debate.

Virtual Pets

Virtual pet games began as a philosophical question: how can a computer program simulate a life-form? One of the most famous examples of these experiments is *John Conway's Game of Life* (1970). Simulating life on a grid, individual cells reproduce and die according to four simple rules. These parameters gave birth to various strategies, including cells capable of motion and endless reproduction.

Commercial virtual pets focus less on philosophical questions and more on resource management. Typically, they entail the maintenance of charismatic virtual fauna based on real or imaginary animals. The first widely commercially successful virtual pets for the personal computer were produced by PF Magic in 1995. The *Petz* series, made up of *Dogz* (1995) and *Catz* (1995), featured stylized cartoon animals that play with toys, eat, and can learn tricks through positive and negative reinforcement. However, excessive use of negative reinforcement or general neglect would eventually cause the

pet to run away. Later games introduced the option to breed your furry companions, producing offspring with randomly assigned characteristics from the mother and father.

The first mobile pet games were little more than computerized key chains. *Tamagotchi* emerged in Japan in 1996 and worldwide in 1997, sparking one of the biggest toy fads of the 1990s. The game consists of a tiny "tama-go" board, a microcontroller, a small four-tone gray LCD screen, and an audio DAC packaged in an egg-shaped plastic case (Silvanovich 2013). Players were tasked with feeding and cleaning up after their pets, while also playing games to boost in-game metrics such as happiness. *Tamagotchi* and their subsequent rival, *Digimon* (1997), responded to care by undergoing different phases of development or evolution. The forms they took were often determined by the quality of care the player provided. Unlike *Tamagotchi*, *Digimon* offered player-to-player battles, with the most powerful adult *Digimon* forms reserved for players who provided the best care. Although these pets appear alive, most of their properties are preprogrammed and thus not truly emergent.

Artificial pet games do not really offer a challenge or a victory condition and may be better categorized as a software toy rather than a game. Will Wright, the creator of *Sim City* (1989), coined the term to describe the entertainment provided by a computer program that does not offer a win state or even an ending. The entertainment from a digital pet comes less from gameplay and more from the affective relationship the player builds with his or her pet. According to psychologist Sherry Turkle, one should

The *Tamagotchi* from Japan was a toy fad of the late 1990s. (Moon Cat/Dreamstime.com)

not dismiss the relationships players develop with their pets as silly or delusional (Turkle 2017). Loving relationships emerge over time, involving imaginative empathy and learning to savor the rough patches and surprises. Whether these surprises come from a living entity or a computer program is immaterial; while the life-form is simulated, the love felt by the player is real.

Virtual Reality (VR)

The term *virtual reality* (VR) is often defined according to the context in which it is used. To an artist, *virtual reality* may have a different connotation than it would for a fiction writer or a computer scientist. However, in the case of video games, the term most notably refers to the use of computer-based simulations to create a perceived experience in real or fantasy worlds.

Some video game enthusiasts suggest that every electronic game is an instance of a virtual reality. Others focus on the creation of games in virtual worlds. For instance, a video game designer might create a game that others could play inside of a simulated world like *Second Life* (2003). Still others might define VR games as those that include haptics, or the use of objects and devices that let users participate more intuitively with games. Examples would include playing a guitar in a real band, as in *Rock Band* (2007); using the controller to swing a golf club, as in *Wii Sports* (2006); or using a controller to dance, as in *Dance Dance Revolution* (1998). Perhaps the most recent and pervasive use of VR with video games relates to the use of hardware or software to produce three-dimensional gaming

interactions (Shelstad, Smith, and Chaparro 2017) in games such as *Beat Saber* (2018) with headsets like the Oculus Quest (2019).

Michael Heim (1993) lists various characteristics of virtual reality, but interaction, immersion, and artificiality are some of the key concepts associated with VR. Ferdig, Gandolfi, and Immel (2018) also highlighted words such as *fidelity* and *presence*. *Virtual reality* is often used interchangeably with terms such as *immersive virtual environments*, *immersive virtual reality*, *augmented reality* (AR), *simulated reality*, and *interactive three-dimensional worlds*. However, there are differences that exist between each of these words; authors who use the term necessarily provide additional qualifications to their definitions as they introduce their topics.

Given its various definitions, there is some debate as to when the term first appeared. Many attribute it to the French playwright Antonin Artaud. Antonin first used the term in his book *The Theatre and Its Double* (1938). Myron Krueger is also credited for using the term “artificial reality” in his creation of *VIDEOPLACE* (1970). However, the concept attained significant attention in the late 1980s and early 1990s, in part due to Jaron Lanier, who founded VPL, the first company that sold VR products (<http://www.jaronlanier.com>). Credit for its rise in popularity is also attributed to Howard Rheingold’s book *Virtual Reality* (1991).

Early work in VR often centered on hardware. Developers created body suits, head-mounted displays (HMDs), and CAVEs (Cave Automatic Virtual Environment) in which participants would interact with virtual worlds or virtual

objects. This was due, in part, to the high technological demands of virtual environments. There were a few VR video games developed at this time, such as *Dactyl Nightmare* (1991), *Virtual Combat* (1993), and *Dactyl Nightmare 2* (1994). However, the cost of head-mounted displays and an attendant to run the game led to a cost of \$4 for four minutes of gameplay, so the game never went much beyond a novelty. With the advent of faster processing speeds, smaller-sized storage devices with increased capacity, and innovative programming, the focus on virtual environments now concentrates on software as well. Researchers and inventors still focus on hardware, such as stereoscopic 3-D; however, development software such as OpenSimulator (2007) and OGRE (2005) as well as synchronous environments such as *Active Worlds* (1995) and *Second Life* (2003) helped redefine VR as a software-based experience. Today, affordable VR systems are appearing commercially, such as the Oculus Go and the HTC Vive, making VR a viable platform for games.

VR applications are used widely in experiences that range from education to health care to military training; for instance, flight simulators are used to train pilots. VR applications are also being used to cure people’s fear of heights (Rothbaum et al. 1995), train surgeons (Seymour et al. 2002), explore mock crime scenarios (Mertens and Allen 2008), and treat balance and depression for stroke patients (bin Song and cho Park 2015). New explorations into VR games are investigating the exploration of gaming environments with sound, smell, and touch.

Visual Literacy

Visual literacy is the ability to critically consider, analyze, and judge the value of visual information such as pictures, graphs, images, illustrations, and videos. The concept, originally coined by John Debes in 1969, was then defined as "a group of vision-competencies a human being can develop by seeing and at the same time having and integrating other sensory experiences" (Avgerinou and Ericson 1997, 280). Explicit strategies may be taught to help increase awareness of how to interact with various types of visual data. Previously, educators have mainly focused on teaching individuals how to interact with textual data. To develop text-based literacy, individuals are taught the conventions of how to read and engage with the written word. As text-based data evolves into more multimodal presentations of information, current trends stress the additional importance of considering the value, source, and authenticity of the visual information with which we are presented.

There are commonalities between text-based literacy and visual literacy and

general rules to follow depending on the interaction type. For instance, written languages such as Hebrew and Arabic are read from right to left, whereas Germanic languages are read from left to right. Punctuation informs the reader in terms of prosody, offering cues such as when to pause or break. These conventions are taught, accepted, and followed when interacting with respective texts to help the reader capture the author's intended meaning.

Compounding on text-based rules, additional considerations apply when interacting with visually rich media such as comics and graphic novels, popular forms of entertainment coupling text with illustrations and images to deliver story content. A reader engaged with such a text should adhere to the previously mentioned rules of text while considering additional ones regarding imagery—namely interacting with image panes from left to right and from top to bottom. This process is similar to the textual conventions of interacting with Germanic and Romance texts; however, image panes may be presented in an infinite array of artistic formats. For example, many Japanese manga (oversimplified in English to mean “comics”) are read from right to left. Awareness of these differences and interaction protocols is critical, and knowledge of how to interact with image-rich media can help maximize what the reader takes away from the story.

In addition to comics and graphic novels, other visually rich media, including painting, photography, film, television, video games, and the World Wide Web, are important in modern culture. One popular method critics have used to teach about and discuss art with a

common vernacular is known as the Feldman Method. For more than fifty years, this four-step process has encouraged individuals to *describe*, *analyze*, *interpret*, and *judge* works of art with which they may interact. Applying this type of concrete methodology to an abstract concept such as evaluating art has provided for rich discussions and appreciation of visual media.

The other forms of aforementioned media also stress the value of visual literacy as they are globally ubiquitous and insatiably consumed. Persons savvy in visual literacy skills are more able to navigate and process the data transmitted by these sources. There was a time when the printed word was viewed as irrefutable fact; however, the advent of the printing press and the more recent segue to current technologies, such as Web 2.0 self-publishing, have made people more critical of the information they consume. Likewise, pictures and videos were once considered examples of undeniable truth, yet this trend has also changed and continues in flux given the ability and relative ease with which we can manipulate visual imagery. For instance, Adobe Photoshop is arguably the industry standard software application for editing visual content; referring to an image as “Photoshopped” is common vernacular, suggesting an image is a fake or has been edited or altered. There are internet sites and online communities centered on fostering the exploration of and continuing the discussion about image editing and manipulation. These groups are now expanding to include deepfake content (i.e., the artificial intelligence-based superimposing of images over video), as supporting technologies are becoming cheaper and more easily accessible. As

such, users must not only critically reflect on the authenticity and value of static images but multimodal content such as videos and animated GIFs also require thoughtful and thorough analysis.

One need look no further than the supermarket checkout lane or local bookstore for examples of magazine covers rife with altered images and unrealistic presentations of the human form, possibly raising issues of self-esteem or negative self-image for individuals with poor visual literacy skills. To complicate matters even more, the meaning of an image may also change based on the context or setting in which it is used, even if the original image remains unaltered. As highlighted by Richard Dawkins's concept of the *meme*, a sort of cultural gene, the use of images or visual data may have an impact on our perceptions of their meaning. Websites such as 4chan, Reddit, and Imgur are hotbeds of memes in action, as users develop, alter, and share personalized interpretations of static images and animated GIFs. These communities have created internet sensations such as LOLcats, Rickrolling, and countless others. The rise of mobile technologies and their ubiquitous nature allow images to go viral at breakneck pace, further feeding the cycle of content creation, dissemination, consumption, and remixing, thus introducing new content and starting the process over again.

Of perhaps greatest interest and import in terms of visual literacy application is the synthesis of text- and image-based evaluation methodologies, protocols, and rules in relation to video game technologies. Borrowing much from conventional literacy theory, film and television theory, art appreciation, and the interpretation of comics and graphic

novels, video games are an art form of their own unique accord. Even in their simplest forms, video games introduced new reading requirements, for example, the need to identify and locate the graphical representation of the avatar controlled by the player (see Reading Video Game Imagery). Akin to theories of art critique and evaluation, the appreciation of imagery and importance of quality graphics relies heavily on subjective factors; some users may prefer realism, and others may be drawn to more stylized graphics. Finally, artistic presentation of video game technologies may find users needing to draw from comic book or graphic novel conventions in terms of following stories presented through storyboards or other types of story panels.

However, gameplay often requires that one must possess skills and knowledge known only to those who interact within gaming or virtual worlds. Given the dynamic nature of these environments, there are skills of visual literacy that either must be learned or experienced to truly appreciate them. There are clearly qualities and factors of *je ne sais quoi* at play that future research may help better define, but the process is as complex as positing what makes someone a great athlete or musician. For example, what issues of visual literacy are at play that allow gaming phenoms such as Tyler "Ninja" Blevins to excel at games like *Fortnite* (2017) to the point of earning millions of dollars through streaming play sessions?

Being able to separate fact from fiction in visually rich media environments is necessary given their prevalence in modern society and the general lack of content policing conducted by various media

outlets. The consumer becomes the ultimate judge of what is worthwhile and what is not in the realm of visual literacy, and the analysis and evaluation of visual elements is a deliberate and explicit process. Intelligence in all areas of information consumption is critical in postmillennial society. Given our ties to, dependence on, and general saturation of visual data in modern culture, visual literacy is equally (if not more) important as textual literacy. As more and more mobile media devices permeate our culture and daily lives, visual literacy skills will increase in importance, making the end user the ultimate judge of credibility and merit in regard to content. Acknowledging the importance of visual literacy and fostering its development are critical discussions, we must continue having these discussions as our daily lives continue to be inundated with visual media.

Visual Novels

The term *visual novel* encompasses a range of games that would be considered as different categories in Japan, as it is not regarded as a genre per se but could rather be described as sharing the same novel game system. It could be argued, however, that these games do share enough similar aesthetic and gameplay elements to warrant their grouping underneath the same label, though their ludic experiences do differ. In their current form, these games can be considered as a remediation of the novel format. Although they are text heavy, they equally rely on image and sound, such as soundtrack and voice acting, to convey the proper atmosphere and to highlight the narrative tensions. The player must "read" and sporadically choose one of the few narrative options presented. Such games often feature a branching narrative structure, and each choice has the potential to take the story in a new direction. Therefore, the player's enjoyment of these games is not limited to experience of a single story but rather the sum of different versions of possible stories (Azuma 2009).

Replaying the game is thus part of the core mechanic of these games, and certain titles will even display (part of) their full narrative architecture, such as the

flowchart system used by Chunsoft's *Zero Escape: Virtue's Last Reward* (2012), or at least their possible endings to give the player an incentive to pursue new choice combinations. Although this multiple ending system rewards the player with a satisfactory end, most of these games nowadays have a "true" ending. This requires that the player view all prior endings (or branches), as this provides the last pieces to resolve the overarching plot.

Visually, these games use a particular cartography of the image, involving the use of image banks and dialogue boxes. These games have relied on pre-rendered pictures that can be combined and swapped in sync with the mood and scene described: some background is used to give the action a context, and a character's portrait can alternate between different sets of clothes, facial expressions, and poses. The story will mostly be told through the use of dialogue, which will be usually be confined to boxes limited to one-third of the screen. When more than two characters are present, the displayed portrait may change to reflect the active speaker. The game may also rely on name indication and on a color-coded system to facilitate quick identification of the speaker. The protagonist, who also serves as the in-game stand-in for the player, is rarely depicted on screen, as these games utilize a first-person point of view: the player character's thoughts, voice, and

actions are merely conveyed through text rather than through a voice actor. The occasional exceptions are the cover art of the game and the use of computer graphics (CG), which may switch to a third-person view.

Adobenchā gēmu, which can be translated as "adventure game" (not to be confused with the adventure game genre), incorporates more ludic phases as a plot device meant to slow the progression of the player, usually under the guise of puzzles.

Ren'ai gēmu, which can be translated as "love simulation game," or dating sims, will always be centered on dating and romance. They may add new interactions, but their finality will irremediably be oriented toward the pursuit of a romantic partner.

Walden, a Game

USC Game Innovation Lab's *Walden, a Game* (2017), a simulation and exploratory narrative game about Henry David Thoreau's time at Walden Pond in 1845, was one of the first games supported by the National Education Association (NEA) and the National Endowment for the Humanities (NEH) under their media arts and digital projects for the public programs, respectively. As an experimental game research project, the game was produced and published by the University of Southern California's Game Innovation Lab as part of a decade-long development process.

The game world is a deeply researched recreation of the pond and surrounding area, based on Thoreau's own surveys, period maps, writings, and journals. The world and its natural objects, including twelve thousand plants, trees, and animals, are part of a dynamic simulation that changes over the eight half-seasons of the in-game year. The player must learn how to live in the woods as plants and berries go in and out of season and as various resources become plentiful or scarce during the course of the year. The game arc, which takes about six hours to play, is based loosely on the structure of the book *Walden; or, Life in the Woods* (1854), which focuses on Thoreau's first year of his two-year stay in the woods.

The narrative elements of the game are found by exploring the nearby town of Concord, Emerson's home, and

Thoreau's cabin and by taking on quests that reveal both social and personal contexts for Thoreau's experiment, which took place when new technologies such as the railroad and telegraph were speeding up the pace of life and there was growing tension in the United States around slavery and expansionism. The details of this backstory were created in collaboration with Thoreau scholars and curators, and the game contains edited material from sources that include the letters and journals of Thoreau, Ralph Waldo Emerson, Horace Greeley, Margaret Fuller, Nathaniel Hawthorne, Louis Agassiz, and other contemporaries of Thoreau.

The game is unusual in its design, as the expected *survival* mechanics, such as maintaining food, fuel, shelter, and clothing, are balanced by a set of less expected *inspiration* mechanics, which are generally more passive in nature and include listening to sounds in the distance, reading books found in the forest, interacting with animals, and meditating at special places of solitude deep in the woods. While the player can choose to upgrade the cabin or tools by working odd jobs and purchasing items such as a fancy fishing rod or iron stove at general store, the real object of the game is to find a balance between how much emphasis is placed on these material needs and how much is placed on attention to the more spiritual needs of the inspiration mechanics. Finding that balance is not a onetime thing but must be practiced

throughout the game as the challenge of the changing seasons increases the emphasis on the material needs.

The characters in the game are voiced by a cast of actors, including Emile Hirsch as Henry David Thoreau, Jim Cummings as Ralph Waldo Emerson, and Misty Lee as Sophia Thoreau. The game was released for Windows PC and Mac OSX on July 4, 2017, which was the date in 1845 when Thoreau began his experiment in living at the woods. A PlayStation 4 release followed in May 2018. A companion curriculum supporting the use of the game in classrooms was released by Journeys in Film in December of 2017.

Walkthroughs

A video game walkthrough tells a player, in detail, how to complete a game. This usually consists of directions on how to progress that can include movements (which way to turn, what door to open, etc.); solutions to puzzles needed to continue forward, locations of crucial objects or areas, and revelations of traps, enemies, or other obstacles that will impede the player. At its core, a walkthrough is mostly concerned with forward progress, guiding a player through the game world or narrative threads that

need to be pursued to reach the end of the game. Other elements are often included within a game walkthrough: tactics to combat enemies, instructions on how to improve a player's character, or statistics for a piece of game equipment can appear. These elements can be extracted from a walkthrough section without compromising its utility, although they will regularly have separate sections earlier in a game guide.

Walkthroughs can follow a critical path or cover every possible event and location in a video game (the 100% walkthrough). A critical path walkthrough focuses on the most direct way to get to the end of a game. It will eschew side quests, noncritical areas, or any other aspect of the game that is unnecessary to simply reach the end. A complete, or 100 percent, walkthrough will cover every secret and location, even those that are not essential to finishing the game. A complete walkthrough is an effort to ensure that a player knows every aspect of the game world. Many video games have multiple end scenarios that are revealed depending on the actions of a player (e.g., the order in which they are taken or the manner in which encounters are dealt with). A critical path walkthrough will usually only address a single ending, whereas a 100 percent walkthrough reveals the different prerequisites for different end scenarios.

A video game with a linear progression (such as those of the *Halo* series) has less need of a walkthrough than games with worlds that can be freely explored, such as *Borderlands* (2009) or those of the *Grand Theft Auto* series. A linear game has few choices for the player to make, and the path forward is the only one available; consequently, a walkthrough

for such a game is mostly useful for revealing what challenges lie ahead for the player. How many and what type of opponents are in the next area, for instance, is of much greater interest than where to find that next area.

Players in an open-world (or “sandbox”) game will be served well by a walkthrough that details the interactions that await them in the various locations available as well as what opponents they may face. This information can be accompanied by suggestions as to what order to attempt these interactions (especially if it is a critical path walkthrough), although the structure of the game may be such that the order bears little consequence on the overall gameplay.

It is difficult to track down the first publication of a walkthrough for a video game, but the walkthrough was undoubtedly pioneered in one of the early video game magazines. A likely candidate is *Computer Gaming World* (CGW), which appeared in 1981 and was geared toward PC games, changing its name to *Games for Windows* in 2006 before stopping its printed format in 2008.

In the first issue of CGW there is a review/guide for the game *B-1 Nuclear Bomber* (1980), a two-page article that includes tips for not only how to play but also how to reprogram the game to make it harder. The second page provides a map to help players plan better routes to targets. Although extremely basic, this can be considered an early walkthrough with its information provided to help a player succeed more efficiently.

A more explicit example of an early walkthrough is the first issue of *Nintendo Power* magazine, published in 1988. The pages include a game guide to *Super Mario Bros. 2* (1988) for the Nintendo

Entertainment System (NES) that is almost indistinguishable from its modern counterparts. Maps, moves, items, enemies, tips, and secrets are all included in a very visual format akin to the strategy guides that came after it. The same issue also details the “second quest” of *The Legend of Zelda* (1986), a harder version of the game that is available after beating the game once. Again, there are maps and walkthrough information to guide a player through the game areas, and it points out problem areas and routes as well as where to pick up various items.

With the advent of published strategy guides dedicated to single video games, walkthroughs became more robust. As games have become more complex, walkthroughs have had to keep pace. The open-world game *Fallout: New Vegas* (2010) has a game guide published by Prima Games that is 448 pages long and covers in detail every one of the game’s hundreds of missions and unique locations.

War

War is a conflict between at least two groups that is carried out through violence. The conflict aids the groups in

solving, clearing, or overcoming differences between them. The measures of violence employed are of nonsymbolic nature and are targeted at the individuals of the group conceptualized as the enemy. Because war as a form of action and its narrative is so substantially interwoven with subject, society, and politics, it is natural that reflections on and interpretations of culture are closely connected to the discussion of war. Thus, the history of games in a broader sense is permeated by a metaphorical or comprehensive discussion of war, and it is moot to consider whether the competitive nature and the oppositional principle of a game reproduces the martial structure or whether the opposite is true and the principle of playful dispute in competitive games culturally and historically preceded martial conflict.

In this sense, many of the oldest known board games (such as Wéquí, Go, Senet, Mehen, the Royal Game of Ur, and, of course, chess) must be interpreted ambivalently. They may be seen as abstract exercises with the goal of building personality, in which the playing subject trains his abilities in anticipatory and planning actions in a situation of competitive character in which two parties acting opposite to one another are in the center of the game metaphor. This conceptualization of games historically leads to a modern understanding of video games. Their ability to represent and simulate as well as their often narrative settings refer back to the concept of an abstract, symbolic, and binary opposition. At the same time, all games may also be seen as abstract models of martial actions, in which tactical, strategic, and operational knowledge is chosen or simulated.

In many traditional and mythological tales (as well as in video games), war functions as a form of dispute: war is seen as a cosmic, archetypal, or natural principle of the different, oppositional, and antagonistic. In contrast, there are positions that see war as a disruption of natural harmony; it is an unnatural, abnormal condition of society and subjects. Consequently, one's view of war is highly dependent on a general perspective of world order—is war a natural condition (according to Thomas Hobbes) or is peace (according to John Locke)? A change of perspective consequently shows that war is not a condition of the subject and its community but rather an operational condition that is part of policies of control and order (according to Jean Jacques Rousseau).

One change in the conceptualization of both war and games is connected to the beginning of the Enlightenment. Because of the beginning of *rationalization*, the perspective on war also changed. One significant position is that of Carl von Clausewitz, who reasons that war is no longer based on natural law or an atavistic cultural formation that culturally shapes humans. From Clausewitz's perspective, war cannot be seen as detached from (national and state) politics. Here, war is conceptualized as a political and rational act of violence in which one's own political will is forced on the opponent, at the same time recognizing that the opponent is fighting with the same motivation. The decisive point in this rationalization of war is the change from the *art of war* to the *science of war*. Here, warfare is changed into a rationally operated, postheroic, rule-governed, and functionally logical practice. As a consequence, the conceptualization of the

game also changes. Games are seen more and more as arenas of action within which postulates of the science of war can be reproduced or internalized as didactical trial actions. In video games, we can find both of these conceptualizations: at the level of narration, there are often *mythological* as well as *rational* conceptualizations; on the level of the program, game mechanics, or the algorithm, war is a scientific, rule-based, and knowledge-based series of events happening in the tradition of the board games and war simulations of the early seventeenth and eighteenth centuries.

The most well-known examples (apart from the reevaluation of chess in European cultural history) are the war board games that were developed in the mid-seventeenth century. Early examples are Georg Venturis's 1797 *Regeln für ein Neues Kriegsspiel für den Gebrauch an Militäranstalten* (*Rules for a New War Game to Be used at Military Facilities*) and the game by Johann Christian Ludwig Hellwig, *Versuch eines aufs Schachspiel gebaueten taktischen Spiels von zwey und mehreren Personen zu spielen* (*Attempt at a Tactical Game for Two and More Persons, Based on Chess* [1780]). Although these games were based heavily on chess and relied on the playful internalization of military scientific paradigms during training, they were followed by a transformation from chess to war simulations as seen in the war board game developed by Leopold Georg Baron von Reiswitz and his son Georg Heinrich Leopold Freiherr von Reiswitz, *Anleitung zu einer Mechanischen Vorrichtung um taktische Manoeuvres sinnlich darzustellen* (*Instructions for a Mechanical Device to Portray Tactical Maneuvers Sensually* [1812–24]). These games not

only successively integrate coincidence and probability into their simulation of war, but they also increase the complexity of the rules and the degree of detail in the reproduction, add limitations to the visibility of the opponent's lineup and movements, and encourage the flexible reproduction of real scenarios. More important, these games need to be interpreted as scientific and rational didactic model areas of the new science of war.

This trend grew in the nineteenth century. War board games increasingly lost their playful or didactic character and more and more became simulations with reference to the real world. In Europe, wargames were employed in the logistical and strategic planning of actual wars, for example, during the Franco-German War of 1870–71 as well as in preparation for World Wars I and II. These simulations were also the predecessors of today's tabletop games, wargames made of tin soldiers, model landscapes, and differentiated rules. One of the well-known examples of this trend is the "Floor Game" by H. G. Wells, to be played with figurines in a model landscape with spring breechloader guns: "This further removes the game from the chess category, and approximates it to the likeness of active service" (Wells 1913, 25).

From the mid-tenth century until World War II, another surge of rationalization unleashed a fresh differentiation and increase in the complexity of so-called conflict simulations (cosims). Driven by the development of computers, the establishment of a mathematically founded game theory, the expansion of the strategic-tactical-operational war paradigm with logistical and economical functions (operation research), and more

complex decision models (e.g., by cybernetics), wargames became informative, dynamic simulations of possibilities. This development can also be seen in the civil sector. Fed by strategic board games (e.g., Charles S. Roberts's *Tactics* [1954]) or pen-and-paper role-playing games (e.g., Gary Gygax and Dave Arneson's *Dungeons & Dragons* [1974]), different computer game genres were developed.

In video games, the strategy game genre was present early on and follows the tradition of the wargame (e.g., Chris Crawford's *Tanktics* [1978]). Together with the tactical shooting game genre that arose during the 1990s, they exemplify the merging of science and war as theorized by Clausewitz and Edward Luttwak. They portray strategic (strategy games) and operational (development simulations) as well as tactical (tactical shooting games) types of action. Yet, the portrayal of war in video games is more than an extension of the science of war model areas. As wargames are also narratives with cultural interpretations, it is not surprising that they use war as mythical narratives beyond concrete or operational functions.

Warnets

The warnet (short for "warung internet"), or internet café, became a booming business in Indonesia, from the late 1990s until the end of the first decade of the 2000s, following the rise of internet users and high demand for an internet connection, mostly among university students. During its glorious moment, two-thirds of internet users gained their access through internet cafés. Entering into the second decade of the 2000s, the number of visitors to internet cafés in

major cities started to diminish, but internet cafés in second-tier cities and rural areas are still a favorite place for internet users. In 2010, there were an estimated twenty thousand warnets throughout Indonesia.

Warnet is a combination of two Indonesian words: *warung* (stalls) and *Internet*. Basically, this is a place that provides computers with internet connections that customers can rent to do various online activities. However, a warnet is not just a place to rent computer; it becomes a learning center for those who cannot afford a personal computer and internet connection at home. The cashiers and operators of warnets are an important source of information and internet and computer knowledge for consumers. The cashier/operator's knowledge and sharing ability is sometimes the reason why one warnet attracts more visitors than others. Before the government tightened internet regulations, warnets were also the place to trade digital files, such as pirated music and movies, and other illegal content, such as porn and disturbing pictures.

Warnets are also a popular place for someone who needs to find information, especially for their hobbies, through visiting forums. Commonly, in a warnet, there is a list of local forums that contains the needed basic information and internet links, so users may choose which forum suits their need. In case of a gaming hobby, warnets mostly installed popular online games and LAN games commonly used by students and young adults, such as *Counter-Strike* (2000) and *Ragnarok Online* (2002), and some of these warnets were then transformed into game centers. These warnets became the place where players of massively

multiplayer online role-playing games (MMORPGs) and local area network (LAN) games created their clans and guilds, and they became their "head-quarters." Some warnets also sell online game vouchers.

Nowadays, when internet connections are easier to access, and with the shift of gaming to mobile phones, most warnets are closing their businesses. Some still actively use the name "warnet," but often only as a printing and computer-rental kiosk. Others have transformed their business into a Wifi-Corner (WiCo), which is claimed to be a modern type of warnet. The WiCo service providers such as Telkom and WiFi.id use the #Warnet-ZamanNow (modern age internet café) hashtag to increase and promote warnet owners to shift their businesses into WiCo service partners. The WiCo business system is still using the internet café payment model, where visitors pay their fare per hour to use the service.

Web-Based Games

Web-based games can broadly be defined as either games that use an internet connection to update gameplay and provide interaction with other players or games that are delivered through an internet browser. They are a quickly evolving and ever-dynamic genre of digital entertainment, and, as technological breakthroughs continue, more and more titles are being created and lumped into this category. What once was limited to programmers and high-end computer users has now been opened up to the most ubiquitous of devices; social networking sites, modern cell phones, and even handheld gaming devices incorporate elements of web-based gaming. This broad classification of video games includes but is not limited to online games such as MMORPGs, browser-based games, certain console-based games, and even some titles ported to handhelds and mobile devices.

Dating back to the mid-1970s, multiuser domains (MUDs) laid the foundation for modern web-based games. MUDs allowed would-be adventurers to embark on epic adventures and slay digital beasts in fantastic text-based worlds. MUDs predated the graphical-based World Wide Web we know today; as such, users were connected to these games and each other via the ARPANET or through other large-scale computer networks. MUDs continued to evolve, and the mid-1990s saw the advent of the text-based MOO (or MUD, object oriented). These games combined the popularity of text-based MUDs with object-oriented programming, providing unique end user experiences.

The popularity and rapid growth of internet-based technologies exposed a

variety of users to MOOs and related games. The term *World Wide Web* was coined around 1990 (Fischetti 2009), and the true genesis of web-based games may be traced to this time. As graphics technologies increased, more familiar multiuser virtual environments (MUVes), such as *Ultima Online* (1997) and *EverQuest* (1999), were created. MMORPGs—also commonly referred to as MMOs—now include a large percentage of web-based games, with titles such as *World of Warcraft* (2004) claiming more than twelve million global users in 2010. Another popular and less system-intensive form of web-based games is the browser-based or plug-in game. Browser-based games require users to install simple plug-ins, such as Java or Flash, and are used in tandem with web-browsing software.

Web-based games have transitioned from personal computers to console systems over the past few years. The console systems of the three main console makers (Sony, Nintendo, and Microsoft) are all internet-ready and afford gamers the opportunity to play with others from around the world without leaving the comfort of their homes. Increased access to networks and cheaper Wi-Fi access are possible factors spurring on increased usage of these types of games. The recent trend finds web-based games expanding even more quickly as handheld gaming devices and cell phones are able to connect gamers to one another and web-based gaming content.

Web-based games have been presented both positively and negatively in the media. From a negative perspective, in the extreme, some people have played MMORPGs, literally, until death. In 2005, a man in Taegu, South Korea,

played for fifty straight hours until he died of exhaustion, and in 2007, a Chinese gamer, Xu Yan, died after playing online games for fifteen straight days. Finally, some have argued that the availability of online games has reduced worker productivity. Other reports contradict these claims and suggest that playing online games help sharpen and refocus workers' minds. Research also suggests that online games can lead to intrinsic motivation (Dickey 2007), collaboration (Papastergiou 2008), and the skills, behaviors, and strategies necessary to live in a complex world (Schrader and McCreery 2008).

Weisbecker, Joyce (1958–)

Joyce Weisbecker developed several games for RCA and is currently considered the first woman to work as a commercial video game developer. The daughter of RCA engineer Joseph Weisbecker, who had himself worked on the development of home computer and video game systems, Joyce Weisbecker was afforded many early opportunities. Her father developed several computer system prototypes as after-hours projects and showed his daughter how to program on these machines. RCA later developed the elder Weisbecker's prototypes into multiple products, including the Cosmac VIP, a kit with which consumers could build their own personal computers, and the Studio II, a game console. Joyce Weisbecker's first two games, *Snake Race* and *Jackpot*, were included in the manual for the RCA VIP. RCA did not pay her for these initial games. However, later projects, including the quiz game *TV*

Schoolhouse I, which she completed in August 1976, earned the high school graduate status a paid contract. Weisbecker worked with pen and pencil, handwriting code and working with one of her father's computer prototypes.

TV Schoolhouse I was an educational quiz game conceived by the elder Weisbecker to leverage the textbook publishing projects and reputation of RCA subsidiary Random House. Joyce Weisbecker developed the quiz game and also produced two further games in October 1976: *Speedway* and *Tag*. These games tested the graphics capabilities of the computers and Weisbecker's creativity. The cars in *Speedway*, for example, appear as simple rectangles, much like the cars in Exidy's *Death Race* (1976) arcade game. While Weisbecker's father had suggested the idea for *TV Schoolhouse I*, *Speedway* was a design she conceptualized, developed, and pitched herself. *Tag*, a much smaller game, was included on the same cartridge as *Speedway*. In 1977, she programmed her last three games for RCA; *Sequence*, *Slide*, and *Sum Fun*, which were released in the RCA VIP Cormac Game Manual, sold as a supplement to the VIP's standard documentation.

With the end of her contract with RCA, Weisbecker chose not to pursue game development further, turning her focus to her university classes at Rider University, where she double majored in computer engineering and actuarial science. At the time, the industry was new and relatively unstable. For Weisbecker, a game development career at the time would have meant living at home, personally copying game manuals and cassettes, and mailing out games to stores and customers. Instead, after

graduating, she pursued a career in actuarial science, later returning for a bachelor's degree in electrical engineering and a master's in computer science.

West and Zampella v. Activision

Jason West and Vince Zampella, founders of the studio Infinity Ward, released *Call of Duty: Modern Warfare 2* (2009) and were fired from their own studio by parent company Activision, allegedly for "breaches of contract and insubordination." West and Zampella then sued Activision for \$36 million, claiming that their firing was to prevent Activision from having to pay their bonuses. After West and Zampella were fired, forty-six Infinity Ward employees, almost half the company's staff, abruptly quit and left the company. The "Infinity Ward Employee Group," made up of thirty-eight current and former employees, also decided to sue Activision for between \$75 million and \$125 million in compensatory damages for unpaid bonuses from *Call of Duty: Modern Warfare 2*.

Activision countersued West and Zampella, claiming that they were trying to steal away the Infinity Ward team for their own gain, and also named Electronic Arts (EA) as part of the lawsuit,

for conspiring with West and Zampella. Overall, around \$1 billion was at stake in the *West and Zampella v. Activision* suit, as West and Zampella's winning of the suit would give them the power to stop the development and release of future games in the *Modern Warfare* settings of the franchise.

The trial's date was set for May 23, 2011, but was then rescheduled to December 14, 2011, and then later to March 29, 2012, and then to June 1, 2012. On March 31, 2012, while waiting for the case to go to court, the two parties settled out of court, though the details of the settlement remained undisclosed. During this time, *Call of Duty: Modern Warfare 3* was in development and was released November 8, 2011.

In 2010, West and Zampella started a new company, Respawn Entertainment, and thirty-eight of the forty-six employees who left Infinity Ward came to work for them. Respawn Entertainment's first game was *Titanfall* (2014), which won over sixty awards after it was revealed at the 2013 Electronic Entertainment Expo (E3).

Wii. See Nintendo Wii

Wii Sports

In 2006, when Sony and Microsoft were marketing their new consoles' realistic graphics and online capabilities, Nintendo chose to prioritize casual fun and off-line multiplayer experiences with a new gestural interface called Wii Remote, which attracted new kinds of players and changed the *ethos* of game culture as a whole. Released as a pack-in game with the new console, *Wii Sports* was the flagship of Nintendo's revolutionary shift toward more inclusive and performative game design, with five minigame sports simulations (tennis, baseball, bowling, golf, and boxing) that brought people of all ages and genders together. The game was a key component of what Jesper Juul called the "casual revolution," defying the limits between hardcore/casual video games and questioning the prejudices implied in such categorizations, thanks to a juicy, intuitive, and addictively mimetic interface: "fun in new ways, because players can learn from watching each other, because failure becomes an enjoyable spectacle, and because they become more immediately social" (2009). In an increasingly individualistic world, where playing games was becoming more of a self-centered experience, *Wii Sports* recreated the social camaraderie of early arcades, where the gathering together of different players around a screen, in a shared space, was key. In addition, numerous scientific studies have quantified health and social benefits related to the game, especially among older adults and nontraditional gamers (Schell et al. 2016).

By choosing to promote the Wii with a mimetic sports simulator, Nintendo

reclaimed the real-world player space (as opposed to the virtual screen space) as the center of game culture, making the best of the fact that millions of players already knew the basic rules of tennis or bowling and could therefore focus on the fun and often hilarious movements of their bodies in front of (and not only on) the screen: kids, parents, and grandparents played and laughed together in an unprecedented scale in game history. This unique celebration of diversity through failure, for comedic purposes, links *Wii Sports* with a longstanding tradition of visual humor that goes back to *commedia dell'arte*, pantomime, and slapstick: not by chance, great silent clowns such as Chaplin, Lloyd, and Keaton released immensely popular movies making fun of the very same sports featured in Nintendo's game (although the most Wii-like parody of tennis takes place in *Monsieur Hulot's Holiday* [1953]). As proven by Seán Crosson in his analysis of sports and film (2013), mocking sport via different kinds of parody enables audiences to question the cultural capital and power dynamics so deeply rooted in contemporary societies. Therefore, *Wii Sports* can be read not only as a humorous and socially empowering take on bodily performance in video games but also, and more importantly, as a critique of the competitive, patriarchal, and agonistic culture of hardcore sport games that “turn the unquantifiable into rationalized calculations and code, to give the gamer the sensation of control and direction they lack in relation to the sports they follow, as well as other aspects of the capitalist society in which they live” (Crawford 2015). Against the male-centered for-profit homogenization of sport games as

a power-drive, playing *Wii Sports* will always be an alternative form of resistance, where the score is not measured in points but in laughs.

Williams (Company)

Williams Manufacturing Company was established in Chicago in the early 1940s. Founded by Harry E. Williams, the company initially specialized in electromechanical games and pinball conversions before expanding to pinball manufacturing. In 1964, Williams was purchased by the Seeburg Corporation, a jukebox manufacturer, and reorganized as Williams Electronic Manufacturing Division. In 1973, it made its first foray into the arcade video game market with

Paddle-Ball—a *PONG* (1972) clone. The company was incorporated in 1974 as Williams Electronics, Inc., a wholly owned subsidiary of Seeburg. Following the latter's bankruptcy in 1979, Williams was spun off as an independent entity. By 1981, it was the leading manufacturer of pinball machines in the United States.

In 1980, the company released Eugene Jarvis's *Defender*. The fast-and-furious side-scrolling shooter quickly went on to become one of the most popular games of the time. It was followed up by such titles as *StarGate* (1981)—Jarvis's sequel to *Defender*—and later by *Joust* (1982), *Sinistar* (1982), and *Robotron: 2084* (1982). To accommodate the rising demand for video games, Williams cut down its pinball production. However, by late 1982, the arcade video game market slowed considerably and eventually crashed the following year (see Crash of 1983). The company posted losses for the next few years, but thanks to renewed public interest in pinball machines, management turned the tide in 1986. In 1988, Williams's parent company, WMS Industries, Inc., purchased its main competitor, Bally/Midway, the pinball and video game division of Bally Manufacturing Company. The production of pinball tables continued under the Williams and Bally names, and Midway developed video games for the home and arcade markets.

In 1991, Midway absorbed Williams's video game division, and WMS Industries created Williams Gaming, which manufactured pinball tables and slot machines. Throughout the 1990s, casino equipment was steadily becoming the company's focus, until it decided to leave the video game business in 1998. At that time, Midway Games, Inc., was spun off and became an independent company.

Williams Gaming made a final attempt to revitalize the dwindling pinball sales with the hybrid Pinball 2000 platform, combining pinball tables with video game elements. In the face of rapidly dwindling sales, the company discontinued its pinball business in 1999 and, under the name WMS Gaming, focused exclusively on slot machines.

Williams, Roberta (1953–)

Roberta Williams founded the computer game company Sierra On-Line with her husband, Ken Williams. She designed a number of important graphical adventure games and is considered a key figure in the history of the genre.

In 1979, IBM programmer Ken Williams purchased an Apple II with the intention of developing a Fortran compiler. However, Roberta began playing text-based adventure games and quickly realized the computer's graphic capabilities could be leveraged for an enhanced, graphic-based adventure game. Over a three-week period, she wrote a script for a game and then convinced Ken to assist in development in his off-work hours. The couple released the game as *Mystery*

House (1980) under the brand On-Line Systems (later Sierra On-Line). The game proved a commercial success, selling fifteen thousand copies, and helped establish Sierra as a key player in the growing computer software and computer game business.

Throughout the 1980s and 1990s, Roberta Williams developed over twenty games published through Sierra On-Line. She is perhaps best known for the highly influential *King's Quest* series, which includes eight titles published between 1984 and 1998, and *Wizard and the Princess* (1980), which is sometimes called *King's Quest 0*. The *King's Quest* games follow the royal family of the Kingdom of Daventry, with the story covering multiple generations and an expansive geographic landscape. The series was integral to establishing Sierra's role as a key player in the U.S. video game and software market. Further, Williams designed the computer game *The Dark Crystal* (1983), based on the 1982 Jim Henson film of the same name; the game went on to win 1984 Best Computer Adventure at the Arkie Awards. Reportedly, Williams had designed the game over roughly a month before turning it over to the development team.

Williams's edutainment title *Mixed-Up Mother Goose* (1987) featured her on the cover in the role of Mother Goose. Sierra remade the game multiple times, and it was a critical and commercial success. The game was recognized with the 1991 Software Publishers Association Excellence in Software Award for Best Early Education Program, and by 1996, Sierra had sold five hundred thousand copies of the game. Williams designed a number of other games, including the *Laura Bow* series, and the full-motion video game

Phantasmagoria (1995), which she has called her favorite design.

While Williams herself was prolific, Sierra On-Line was even more so. The founders recruited writers and developers, including Jane Jensen, Al Lowe, and other notable figures. Williams's influence on the adventure game genre includes her own numerous titles as well as her work in founding and running Sierra On-Line, one of the most important publishers and distributors of computer games. Sierra On-Line was acquired by CUC Software in 1996, but Williams continued working as a designer at Sierra until she retired in 1999. Postretirement, Williams has largely stayed out of the public eye; however, she did contribute to the design of the Facebook game *Odd Manor* (2011), on which Chris Williams, Roberta's son, and her husband, Ken Williams, served as lead engineer.

Salter, Anastasia. "King's Quest: Narrative." In *How to Do Things with Video Games*, edited by Matthew Thomas Payne and Nina B. Huntemann, 29–35. New York: New York University Press, 2019.

World (of a Video Game)

Many video games, like novels and narrative film and television shows, can be said to have a diegetic world, that is, the

imaginary or fictional world in which the work's characters live and where events take place. Such worlds are usually made in support of a narrative, although worlds do not necessarily have to contain stories, and not all of them do. Video games such as those of the *Sim* series and other sandbox games allow players to build imaginary worlds, but there is no predetermined narrative that occurs there, although the player's experiences and interaction within the world may constitute something like a narrative.

Video game worlds are necessarily composed of several things: some kind of geography, inhabitants, action, and logical consequences that are the outcome of actions. Every game world has some kind of space in which the game's action takes place, from a simple blank playing field that is a single screen in size (as in many early arcade games), to a verbal description (in the case of text adventures), to a vast, elaborately detailed world with hundreds of thousands of players (as in massively multiplayer online role-playing games [MMORPGs]). These areas are displayed on-screen, and many games, especially adventure games, require exploration of the game world, where other characters are encountered, objects are found, and quests are completed. Sometimes the revelation of game world space is the game's main objective, although it is more likely to be a subgoal required by other game goals. In many games, especially those with three-dimensional graphics, there is usually some sense of what lies beyond the game world space that the player's avatar can actually visit, conveyed by backdrop imagery (depicting an extension of the game world out to a distant horizon) that is placed around the edges of the active game area.

The inhabitants of the game world include the player's avatar (or avatars), the avatars of other human players, and the non-player characters (NPCs) controlled by the game programming. All characters, whether avatars or NPCs, usually have some kind of purpose, motivation, and goal-oriented behavior, which may help or hinder that of the player's avatar (or the player's intervention, as in the case of sandbox games in which the player does not control an avatar directly). The characters initiate action within the game world, although action can also be initiated by the game program's direct control of the game world itself—for example, changing weather conditions, a diurnal or seasonal cycle, or events such as earthquakes or tornadoes (as in *SimCity* [1989]). Quite often, the action of the game world's characters directly affects the state of the game world itself, and a particular game world state may even be the game's objective.

Finally, a game world will operate according to some logic that it uses to assign consequences to actions taken by the game world's characters. These consequences are usually consistent and can be expected in advance once the player learns how the world works. Through knowledge of these consequences, players can make gameplay choices that move the game world's state in a desired direction. The game world's logic determines much of the gameplay experience, and it may also shape the look and feel of the game world itself, suggesting guidelines for design aesthetics. Other aspects of the game world controlled by the game engine include the physics of game events, the automatic positioning of the implied camera that controls the player's

point of view, artificial intelligence (AI) controlling NPCs, and the player's interaction with the world.

HISTORY OF VIDEO GAME WORLDS

Although text adventure games created their worlds through words, similar to literature, fast action and a feeling of immersion and immediacy require a visual representation of a game's world. Over time, the visuals of video game worlds grew from the single-screen games of the 1970s, to scrolling screens that revealed a much larger world beyond the edges of the screen (beginning with *Super Bug* [1977]), to worlds made up of multiple screens that cut one to the next (beginning with *Adventure* [1979] for the Atari VCS 2600), to three-dimensional worlds with z-axis depth that extends into the screen (as in *Maze War* [1974], *Battlezone* [1980], and *Myst* [1993]). With greater memory available in computer discs and diskettes and the move from cartridges to CD-ROM-based games in the late 1980s, worlds were able to become even larger and more detailed, allowing more player involvement and engagement. Finally, as online games developed into multiuser domains (MUDs) and, later, MMORPGs, their game worlds were inhabited by an increasing number of player characters, and many became persistent worlds, operating continuously, twenty-four hours a day.

Procedurally generated worlds, such as those of *Minecraft* (2009) and *No Man's Sky* (2016), can be extremely vast and may contain endless landscapes or billions of planets, which are generated mathematically from seeds and algorithms. The size and complexity of these worlds is so vast

that no one person can experience more than a small fraction of the events occurring in them. The ongoing existence and high degree of interactivity of these worlds, as well as the necessity of choosing what is seen or experienced from myriad simultaneous events, creates an experience quite unlike that of the imaginary worlds experienced through traditional media like books, films, and television shows.

In traditional narratives involving imaginary worlds, the main character is often a traveler to a new world, through whom the audience experiences the world vicariously. In earlier worlds, the main character tended to be a traveler and observer; as time went on, and especially into the twentieth century, main characters became more actively involved in the imaginary worlds they visited, even becoming agents of change in those worlds. Video game worlds can be seen as extending that interactivity to the audience members and, thus, can be seen as another advancement of the imaginary world tradition begun thousands of years ago.

World Cyber Games

The World Cyber Games (WCG) is an esports tournament that was held annually from 2000 to 2013 and again in 2019. Unlike many tournaments, the WCG hosts competitions in multiple titles—the yearly selection of which reflects game industry trends as well as publishers’ willingness to lend their intellectual property—and asks players to compete on behalf of their country rather than the professional organizations to which they are contracted. In this way, the WCG was (and is) billed as a kind of “Esports Olympics,” invoking competition among nation-states as part of a broader ideal of global humanism. “[The WCG’s] vision is to contribute to making the world better by offering joy and helping settle conflicts,” as the company’s current mission statement reads. “[We] seek to establish WCG not merely as a contest of esports matches but also as a festival for people all over the world to live in harmony” (World Cyber Games n.d.).

The first WCG event was held in Everland, a theme park in Yongin, South Korea, in October 2000. At the time, interest in competitive gaming was growing, and many players and commercial actors invoked esports as a way to legitimate professional gaming as a worthy cultural pursuit (Taylor 2012). This often resulted in emulating the practices, cultures, and institutions of so-called traditional sports.

Given the worldwide (though still niche) popularity of professional gaming, an Olympic-style event was an inevitability. In South Korea, where the esports industry was most mature due to a confluence of social, technological, and economic factors, the Ministry of Culture and Tourism, the Ministry of Information and Communication, and the Samsung corporation joined forces to put on WCG (Jin and Chee 2009). Over the next decade, the WCG grew dramatically in size and scope, becoming one of the most prestigious esports tournaments in the world. Whereas, in 2000, 174 participants representing seventeen countries competed, these numbers blossomed to 800 players from seventy-eight countries at the tournament’s peak popularity in 2008.

However, the WCG began to lose ground in late 2000s. Increasing competition from independent tournament organizers such as Dreamhack, ESL, and MLG and new first-party tournaments hosted by game publishers such as the League Championship Series siphoned away some of the WCG’s prestige. Moreover, as the esports industry matured and the number of tournaments grew, top players often prioritized competing with professional teams rather than one-off nation-based ones. The situation was made worse by an unsuccessful television venture (a reality show titled *WCG Ultimate Gamer* that, regrettably for all, ran for two seasons on SyFy in 2009 and 2010) and mismanagement from WCG’s executive staff, who were infamously described by one corporate partner as “impossible to work with” (O’Neill 2014). Finally, in 2014, WCG announced that the organization was going on indefinite hiatus.

It is unclear whether the current revival of the WCG, which is organized by the

South Korean game publisher Smilegate, will have any staying power. Even so, its underlying motivation—the conscious emulation of traditional sports’ most renowned mega-events—lives on in tournaments like the Overwatch World Cup and the International Olympic Committee-sanctioned Intel World Open. If the World Cyber Games originally represented a vision for what a global esports event could someday be, that vision has since begun to materialize, with or without it.

World of Warcraft (WoW)

World of Warcraft (WoW), developed by Blizzard Entertainment, is a massively multiplayer online role-playing game

(MMORPG), one of the most popular online games of its genre, and one of the biggest successes of the video game industry, with a peak of over twelve million players in 2010. *WoW* was officially launched on November 23, 2004, in North America, Australia, and New Zealand and in Europe and Asia in 2005; it is distributed in seven languages.

WoW takes place in a persistent world, with anywhere from five thousand to thirty thousand players online simultaneously at any given time on each of the servers (or “realms”) hosted by the company. The game’s main goal is to increase the power of the player’s character. Progression is calculated with experience points (Xp) between the levels 1 to 120, but players can evaluate their progression by the value of the equipment they own, their skill points, their reputation within different factions, honor points, and so on. Players are invited to undertake quests, complete dungeons, kill monsters and other players, make money, discover the world, and interact with other players. When characters reach the highest level, in what is called the “End-game” (also known as the “Elder game”), players usually concentrate their activities on raiding or completing top-tier dungeons and fighting in arenas or battlegrounds. In an arena, a team of two, three, or five players has to kill another team in hand-to-hand fights, while in a battleground, one team of more than ten players has to attack or defend specific spots, capture the flag, or control bases and resources.

WoW is based on the *Warcraft* series of real-time strategy (RTS) games, extending their world into an MMORPG. *WoW* features three modes of gameplay: player versus environment (PvE), player versus

A screenshot from *World of Warcraft*. (Courtesy of Mark J. P. Wolf)

player (PvP), and role-playing (RP). The game's logic and vocabulary are inspired by the medievalist fantasy genre and the *Dungeons & Dragons* (1974) tabletop role-playing games (RPGs) created by Gary Gygax and Dave Arneson as well as by previous MMORPGs, especially *EverQuest* (1999). A vast mythology has been created for *WoW* to explain the history of wars, alliances, leaders, and so on, and it defines the spatial and social organization of the game.

To play the game, players choose an avatar in one of two factions, the Alliance or the Horde, and between races in each faction: the Alliance includes human, dwarf, night elf, gnome, and draenei, and the Horde includes orc, undead, tauren, troll, and blood elf. Characters in each race can be divided into ten classes: druid, hunter, mage, paladin, priest,

rogue, shaman, warlock, warrior, and death knight. The choice of class has a big impact on the player's role during combat, such as causing long-distance damage, tanking or fighting, healing, or crowd controlling. Players also must select their character's gender and some physical features, and, once in the game, they can choose up to two specific professions per character and build a talent tree.

Part of the game can be played alone, but it is also based on social interaction between players, who are invited to gather together in temporary groups or more permanent groups called "guilds." Guilds are managed by players and are more or less organized, populous, and regulated according to their leaders, who determine the type of guild and its rules and goals. Two classical oppositions are

the raiding guild, based on hard progression, and the casual guild, based on socialization. The game has also an economic system principally dependent on trading between players. The currency is called “gold,” and some players, who specialize in collecting gold to sell for real-world currency, are called “gold farmers.” Gold farming and selling characters are forbidden by Blizzard Entertainment, although a large market for it exists on the internet, which is difficult to police because of the scale of the game and its online culture.

Developer and publisher Blizzard Entertainment, the maker of *WoW*, is headquartered in Irvine, California. It was founded in 1991 by Allen Adham, Michael Morhaime, and Frank Pearce under the name Silicon & Synapse, which was changed to Blizzard Entertainment in 1994. Before *WoW*, Blizzard developed a number of games, including *Warcraft: Orcs and Humans* (1994), *Warcraft II: The Tides of Darkness* (1995), and *Warcraft III: Reign of Chaos* (2002) as well as *Diablo* (1997) and *StarCraft* (1998), which both began series of their own. In May 2016, Blizzard also released a team-based multiplayer first-person shooter (FPS) called *Overwatch*.

Blizzard has released seven *WoW* expansions. The first two were *World of Warcraft: The Burning Crusade* (January 2007) and *World of Warcraft: Wrath of the Lich King* (November 2008), which, according to the company’s official statistics, sold four million copies in its first month. *World of Warcraft: Cataclysm* (December 2010) was followed by *World of Warcraft: Mists of Pandaria* (September 2012), *World of Warcraft: Warlords of Draenor* (November 2014), and *World of Warcraft: Legion* (August 2016). The

last expansion to date is *World of Warcraft: Battle of Azeroth* (August 2018), and according to Blizzard, it sold 3.4 million units in its first day, making it the fastest-selling *WoW* expansion. Each expansion has raised the maximum character level, which is 120 as of 2019, and as new expansions are released, the older ones are being included in the base game.

Blizzard stopped releasing the official number of subscriptions for *World of Warcraft* in September 2015. At this date, *WoW* had 5.5 million monthly paying players. In 2016, Blizzard Entertainment released a movie called *Warcraft*, based on the Warcraft universe, directed by Duncan Jones and produced by Legendary Pictures, Blizzard Entertainment, and Atlas Entertainment. Blizzard also produces derivative products of *World of Warcraft*, such as tabletop games, collectible card games, books, and comics. On August 26, 2019, Blizzard released a “classic” edition of Warcraft that enabled players to experience the game as it was before the expansions. Due to the persistent world and the number of players committed to the game, *WoW* is one of the most researched games in the field of game studies.

World Video Game Hall of Fame

The World Video Game Hall of Fame at the Strong National Museum of Play recognizes individual electronic games of all types—arcade, console, computer, handheld, and mobile—that have enjoyed popularity over a sustained period and have exerted influence on the video game industry or on society in general. The inductees into the World Video Game Hall of Fame stand out for their major impact on the history of video games.

Inductees to the World Video Game Hall of Fame as of 2018 include *Spacewar!* (1962), *The Oregon Trail* (1971), *PONG* (1972), *Space Invaders* (1978), *Pac-Man* (1980), *Donkey Kong* (1981), *Tetris* (1984), *Super Mario Bros.* (1985), *The Legend of Zelda* (1986), *John Madden Football* (1988), *Street Fighter II* (1991), *Sonic the Hedgehog* (1991), *DOOM* (1993),

Pokémon Red and Green (1996), *Tomb Raider* (1996), *Final Fantasy VII* (1997), *The Sims* (2000), *Grand Theft Auto III* (2001), *Halo: Combat Evolved* (2001), and *World of Warcraft* (2004). All inductees are honored in a permanent exhibit at the Strong.

Any member of the public can nominate a game to the World Video Game Hall of Fame. Final selections are made on the advice of the Player's Choice ballot and an International Selection Advisory Committee composed of journalists, scholars, and other individuals familiar with the history of video games and their role in society.

The World Video Game Hall of Fame recognizes individual electronic games that meet the following criteria:

- **Icon-status:** The game is widely recognized and remembered.

The World Video Game Hall of Fame at the Strong National Museum of Play in Rochester, New York. (Debra Millet/Dreamstime.com)

- **Longevity:** The game is more than a passing fad and has enjoyed popularity over time.
- **Geographical reach:** The game meets the above criteria across international boundaries.
- **Influence:** The game has exerted significant influence on the design and development of other games, on other forms of entertainment, or on popular culture and society in general. A game may be inducted on the basis of this criterion without necessarily having met all of the first three.

The Strong honors the games in an annual induction ceremony. In 2018, the World Video Game Hall of Fame published a book entitled *A History of Video Games in 64 Objects* that tells the history of the inductees as part of the longer history of video games. In 2021, the Strong will open a major gallery dedicated to celebrating the members of the World Video Game Hall of Fame within a larger exhibit that explores the history of video games.

The World Video Game Hall of Fame is administered by the Strong's International Center for the History of Electronic Games (ICHEG). At sixty thousand video games and related artifacts and hundreds of thousands of archival materials documenting the history of video games, the Strong's collection is the largest and most comprehensive public assemblage of such items anywhere.

World War II in Video Games

World War II, a multinational armed conflict that lasted six years, from September 1, 1939, until September 2, 1945, has influenced the design, subject matter, and narrative content of video games since the mid-1970s. Early examples of video games set during World War II include *Desert Fox* (1976), *Sea Wolf* (1976), *M-4* (1977), and *M-79 Ambush* (1977), their titles respectively referring to the German field marshal Erwin Rommel, the World War II USS *Seawolf* Sargo class submarine commissioned in 1939, the M4 Sherman Tank predominantly used by the United States during the conflict, and an iteration of Japanese military aircraft. These early games were exceedingly minimalist, presenting the player with undifferentiated depictions of land, sea, or air where point-and-shoot battles occur.

More complex representations of World War II released in the 1980s and 1990s would foundationally structure an array of game genres that included flight simulators, real-time and turn-based strategy games, and first-person and third-person shooting games. Shooting games predominantly place the game player on the side of the Allied powers during the conflict, requiring players to play as infantry fighting for the United States, the Soviet Union, the United Kingdom, or France, combating the Axis-aligned countries of Germany and

Japan, whereas flight simulators and strategy games frequently allow players to operate as pilots and commanding officers fighting on either side of the war. Of the numerous individual battles that occurred during the war, World War II video games frequently focus on major military conflicts, such as the Pacific Theater, the Eastern Front, and the Battle of Normandy, representing these conflicts differently depending on the genre and the technical capabilities of the individual games and the platforms on which they are played. Many World War II video games emphasize an attention to historical detail on multiple tiers, foregrounding the factual fidelity of both the battles in which players participate and the weapons they employ during the conflict, promoting these games as accurate representations or simulations of historical occurrences. Other games, such as Id Software's first-person shooter *Wolfenstein 3D* (1992), actively intertwine history and fantasy, eschewing historical accuracy in the construction of horrifying game worlds where players explore the depths of Nazi villainy.

World War II flight simulators, video games that feature simulated aerial combat based on actual missions flown during the war, achieved early prominence within video game history. Capcom's *1942*, released in video game arcades in 1984 and later ported to the Commodore 64 and the Nintendo Entertainment System (NES), stands as a popular early example of a flight simulator based on World War II; in a vertically scrolling shooting scenario, the player must guide a "Super Ace" plane, designed to resemble a Lockheed P-38 Lightning aircraft, over Tokyo, attempting to destroy the Japanese air fleet during the war's Pacific Theater.

Although *1942*'s simulation of aerial warfare is inherently limited because of the technological restrictions of early arcade and home console systems, later flight simulators incorporate far greater attention to detail in terms of the plethora of controls available to players and the visual representation of the areas over which they fly. Dynamix's *Aces of the Pacific* (1992) allows players to operate multiple types of aircraft flown during the Pacific Theater and choose to play historical missions based on specific conflicts, notable in that the player can play as either Japanese pilots attacking Pearl Harbor or American fighters defending against the attack.

MicroProse's computer game *1942: The Pacific Air War* (1994) expands gameplay beyond the shooter style evident in the aforementioned titles, allowing players to participate in a "tour of duty" mode in which they are required to not only fly and fight in singular missions but also manage the entire aerial fleet through a campaign map. Microsoft's *Combat Flight Simulator WWII Europe* (1998) and its sequels provide players with databases of aircraft, scenery, and statistics, which they can reprogram, allowing user-generated content to enliven the game's replay value. A focus on dynamism and malleability is also evident in *War Thunder* (2013), which emphasizes the diversity of craft that the player can pilot, allowing for the control of over one thousand air, land, and sea vehicles, featuring planes from a dozen countries. It replicates actual missions from World War II, conflicts that precede and follow World War II, and speculative missions that were planned but did not occur.

In contrast to World War II flight simulators, strategy video games, also

known generically as computer war-games, emphasize the tactics and minute operations of military combat, avoiding the player-orchestrated participatory shooting action of the flight simulator genre, allowing the player to oversee large-scale military fronts. Strategy games such as Strategic Simulations, Inc.'s *Panzer General* (1994) feature multiple maps, frequently viewed from an aerial, seemingly omniscient perspective, in which players control a diverse array of military units as they advance on the enemy. Players must leverage health statistics, weaponry, and supplies against one another, applying each element differently to the diversified military units under their control, to effect victory.

Among World War II video games, strategy games most clearly resemble board games, often depicting the battlefield through a hexagonal map; indeed, some of the earliest versions of World War II strategy video games include computer simulations of board games, such as digital versions of wargame publisher Avalon Hill's *Squad Leader* (1977) and *Advanced Squad Leader* (1985). Strategic Simulations' *Computer Bismarck* (1980) is hailed as the first "serious" strategy game designed explicitly for a computer, chronicling the last battle of the German battleship *Bismarck* in May 1941. Like other releases from Strategic Simulations, such as *Panzer General* and *Steel Panthers* (1995), *Computer Bismarck* is a turn-based strategy game in which a single player and the computer (dubbed "Otto Von Computer") or two players successively take turns.

Microsoft's *Close Combat* (1996) sets its action in real time, representing armed conflict between the United

States' Twenty-Ninth Infantry Division and Germany's 352nd Infantry Division after the Battle of Normandy, without allowing a pause between actions taken. Controlling the movement and battle strategy of their troops, determining how they proceed across the varied landscape and in what ways they attack, defend against, and suppress the enemy, the players of *Close Combat* must also take into account the simulated morale of their soldiers, which can lead to acts of heroism or a descent into shell shock. Such attention to minute details is commonplace in a genre known for both its complexity and its passionate, focused following. *Close Combat* was particularly successful in appealing to this dedicated fanbase, with developer Atomic Games and publisher Microsoft releasing over a dozen sequels.

With a focus less on obsessive strategy and more on outright, immediate violence, World War II first-person shooting games popularized the genre in the 1990s. In Id Software's *Wolfenstein 3D* (1992), players must fight their way out of a Nazi castle in the heart of the Third Reich from a first-person perspective. Although *Wolfenstein* features horrifying representations of Axis powers, with the player having to defeat a monstrous mechanized Hitler to win the game, later shooters, such as Treyarch's immensely popular *Call of Duty* franchise (begun in 2003) and Electronic Arts' *Medal of Honor* franchise (begun in 1999), emphasize historical fidelity. These games, which rely on the inherently repetitive core mechanic of aiming and firing, nonetheless lay claim to a strong sense of historical realism.

This sense of realism is evoked through the graphical specificity and first-person

representation of historical battles, such as the Battle of Peleliu Island and the Battle of Stalingrad in *Call of Duty: World at War* (2008), or the storming of the beaches on D-Day at the beginning of *Call of Duty: WWII* (2017). These games blur the boundary between computer animation, Hollywood film, and documentary with the increasingly accurate depiction of World War II-era weaponry, such as Thompson submachine guns and Mosin-Nagant rifles, with mechanical functionality and aural fidelity emphasized; the incorporation of cutscenes that provide the player with relevant dates, statistics, and archival footage concerning the forthcoming conflicts; and the declaration during the games' credit sequences of the historians, military officers, and veterans consulted during the design process. Over time, the historical detail presented has become increasingly emphatic: in the original *Call of Duty*, cutscenes present two-dimensional maps and a detailed voiceover in which the mission and its importance are carefully described, whereas *World at War*'s cutscenes present sweeping three-dimensional animated maps of the world punctuated with real, grainy film footage of soldiers fighting while oversized statistics regarding weapon production and the war's death toll fill the screen. These shooting games are thus able to intertwine a high degree of factual information with fictional character biographies so as to position their digital, interactive representation of war as a more accurate replication of the conflict.

Recent World War II first-person shooters (FPS) have delved more explicitly into controversial subject matter. *Call of Duty: WWII* requires the player and his or her platoon to liberate a concentration camp, a subject rarely depicted

in video games of any genre. And *Wolfenstein II: The New Colossus* (2017) intentionally antagonized conservative Americans through its advertising, imploring them to "Make America Nazi-Free Again," drawing a direct parallel between Donald Trump's supporters and Nazi fascists.

Criticism of World War II video games, beyond highly politicized debates concerning the effects of video game violence, has considered both the ideological effects and historical value of contemporary representations of the war. Multiple scholars criticize World War II games as paeans to militarist ideologies and nationalist jingoism, understanding such games to function as recruitment tools for the U.S. military, imbuing players with a chauvinistic national outlook that supports the military-entertainment industrial complex. Other scholars discuss World War II games as promoting an exploration of the concept of history itself, allowing players to openly explore and alter static, totalizing histories of World War II, the narratives of which frequently remain unquestioned. To these critics, the interactive ability to alter the outcome of major historical events allows the player to investigate and understand the multivalent nature of the history of World War II itself.

Wright, Will (1960–)

William (Will) Wright is an American game designer best known for his *Sim* series of games. Wright was born in 1960 in Atlanta and at age nine moved to Louisiana after the death of his father. Wright graduated from high school at age sixteen and then, over the course of several years, attended Louisiana State University and Louisiana Tech before moving to New York, where he enrolled at the New School in Manhattan. His topics of study were varied and included architecture, engineering, computers, and robotics. In 1981, Wright returned to Louisiana without earning a degree but continued to follow his personal passions and interests.

Wright's earliest design work was completed in 1984 on a wargame for the Commodore 64 home computer system. The game, *Raid on Bungeling Bay* (1984), afforded Wright the opportunity to build maps and create levels. In an interview, when questioned about his experience working on this game, he recalled how building those maps and levels—along with his interest in urban planning—gave him more enjoyment than actually playing the game. Wright formed a company called Maxis Software with game producer Jeff Braun, and in 1989, the world was introduced to *SimCity*. This landmark title afforded players the opportunity to build and run cities and to

experience elements of the "god game" genre hitherto unexplored. Newer versions of the game allow players to sculpt mountains and even plan disasters for their cities, but the primary focus of the game centers on direction and management rather than destruction or violence.

SimCity was the first in a series of simulation games that include *SimEarth* (1990), *SimAnt* (1991), *SimLife* (1992), *SimTower* (1994), and the very popular franchise simply called *The Sims* that launched in 2000. Wright's 2008 project, *Spore*, allows players to develop highly complex creatures from microscopic organisms. These titles are some of the highest grossing of all time, and the original *The Sims* game remains in the global top twenty list, boasting more than sixteen million copies sold.

Although the *SimCity* franchise did well for Maxis, Wright and his partner thought the company could not survive on its own, so they sold Maxis to Electronic Arts (EA) in 1997. Wright worked at EA until 2009, when he opted to leave and found *Stupid Fun Club*, a joint venture think tank between himself and EA, which claims on their website to be "an entertainment development studio" focused on "video games, online environments, storytelling media, and fine home care products." At the March 2018 Game Developers Conference, Wright announced a new mobile game project entitled *Proxi*.

Will Wright is known for having a keen eye on the gaming industry. For instance, in a 1994 interview with *Wired* magazine, he predicted that, by 2009, online games would be the norm, and we can now observe the truth in this prediction. His visionary contributions to the god game genre are immeasurable, and his style of

blending role-playing with real-time strategy game techniques is used to this day.

XaviXPORT

On September 16, 2005, Nintendo CEO Satoru Iwata announced a revolutionary new console that the company would be introducing the following year. It was so revolutionary that the code name for it was “Revolution.” What was revolutionary about the system was its unique motion sensor controller. After the console was released under the Wii name, it was so successful that Sony and Microsoft released their own motion controllers for their individual systems. But while the Wii was indeed successful, it was not as revolutionary as Nintendo wanted to lead to people to believe. A small Japanese company called SSD Company Limited (SSD was short for Shinsedai, Japanese for “A New Generation”) actually released a similar console, the XaviXPORT, in August 2004, roughly about the same time that Iwata was introducing the Wii. But while the XaviXPORT was its first console, the company had been releasing motion sensor products a half decade before that.

The Japanese company, based in the Shiga Prefecture, had been founded by an electronics engineer named Katsuya Nakagawa on December 1, 1995. Prior to starting his own company, Nakagawa had been an engineer at Nintendo, where he had codeveloped twenty patents that had been assigned to the company. Nakagawa brought seven of his Nintendo engineering colleagues with him to his new venture. SSD’s mission was to use

their specialty digital technology for the benefit of society. As a means to this end, they developed what they called XaviX-Technology, which combined human interface sensors, including optical and infrared sensing, which allowed any television to respond directly to the user’s actions.

One of SSD’s first products was *Excite Stadium*, which was licensed to Epoch and released in Japan in 2000. Innovative at the time, the *Excite Stadium*, was one of the first plug-and-plays (a small console that plugged into a television and was ready to play with built-in games). The base unit actually looked like a rectangular base from a baseball diamond. A baseball peripheral was attached to it that allowed the player to “pitch” a physical baseball during a game. Wireless sensors within the ball communicated with the base unit and provided such information as the type and speed of the pitch. A bat that also connected to the base unit via sensors was also provided. *Excite Stadium* allowed people to pitch and hit as if they were in a real game while the rest of the team played on-screen. Radica Games released *Excite Stadium* under the name *Play TV Baseball*² in the United States.

SSD went on to develop and license dozens of games that utilized its proprietary XaviX Technology, but it never released anything under its own brand name. That changed after SSD developed a new console that employed the XaviX Technology. The result was the

\$79.99 XaviXPORT, which was released in September 2005. This new system offered players a video game version of baseball that used physical objects, such as a bat and ball, much like SSD's earlier *Play TV Baseball*². However, while the dedicated *Play TV Baseball*² could only play one game, baseball, the XaviXPORT was capable of playing many different games with the switch of a ROM cartridge.

Each of the game cartridges contained its own proprietary XaviX multiprocessor. The advantage of this was that as new games were developed, they could benefit from having more sophisticated processors without the console itself requiring upgrades. The chips in the first three XaviXPORT cartridges used 8-bit 6502 multiprocessors, which were the same processors that had been used in the Nintendo Famicom. And the results were evident. Critics were less than impressed with the system's graphics and sound capabilities, which they compared to the ten-year-old Super Nintendo Entertainment System (SNES) and the SEGA Genesis.

Despite the low-quality graphics and sound, critics praised the innovative controls of the XaviXPORT. The game library was small, but each game cartridge was packaged with its own unique controller. And while the controllers were indeed distinctive, the mechanics of the system were even more so. The wireless controllers were not connected to the console, which used optical sensors and infrared technology to detect the player's movements and, in turn, respond to the speed and direction of the player's motions.

The initial games for the XaviXPORT were sports games, each packaged with

its own unique and innovative controller: *XaviX Golf* (2005) came with a driver and a putter, *XaviX Bass Fishing* (2006) was packaged with a fishing rod controller, *XaviX Baseball* (2006) came with a baseball bat controller, *XaviX Bowling* (2007) had a bowling ball, and *XaviX Tennis* (2007) was packaged with a tennis racket controller. In addition to sports games, SSD also developed and released two titles that dealt with body fitness. Both were endorsed by and featured actor and martial artist Jackie Chan and were part of a series called *Jackie Chan Studio Fitness: Powerboxing* (2005), which was packaged with a pair of boxing gloves. The other title, *J-Mat* (also known as *Aerostep* [2005]), was a mat that users stepped on for cardiovascular exercises. The package also came with two hand weights that were used in some of the exercises.

In 2006, SSD repackaged the *J-Mat* as the Step Sensor and sold it without the cartridge or the weights. Only one product was ever released for use with the Step Sensor, *Music & Circuit* (2007). In addition to a cartridge, *Music & Circuit* came with a cable to connect a multimedia device, such as an MP3 player, to the XaviXPORT, allowing people to exercise in sync with their own music while using the Step Sensor.

SSD developed an additional fitness program, *XaviX Lifestyle Manager* (2006), which was packaged with a wireless scale that sent data to the XaviXPORT system for weight trends, BMI body fat percentage, and lifestyle analysis. Also included were warm-up circuit trainings and cool-down exercises.

The final software released by SSD was *Eyehand* (2008), which was packaged with two "glove sensors" that allowed the

user's hands to act as controllers for minigames displayed on the television screen. One such game involved the player catching on-screen butterflies. The player waved his or her palms, which were represented on-screen as circles, and when the player moved a circle around a butterfly and closed his or her hand, a butterfly was caught. The object was to catch as many butterflies as possible.

The console found it difficult to compete with the major consoles; neither SSD nor the XaviXPORT had any name recognition, especially since the console was completely devoid of a marketing campaign. And the few stores that carried it, mostly stores that did not carry other video game consoles, usually treated it as a novelty item. Three additional titles, *XaviX Hot Plus*, *XaviXmobile Atama Club*, and *XaviX PowerKIDS*, were exhibited at the Tokyo Game Show in 2009, but they were never released.

Following its experiment with a console marketed under its own brand name, SSD returned to creating unique electronics toys that were sold by other companies and continued to do so until 2010. On September 13, 2009, the company introduced *The Body Conditioner*, a motion analysis system. The company displayed it over the next two years, but there is no evidence that the unit was ever released. In 2011, SSD stopped maintaining its corporate website but continued sell its XaviXPORT at a greatly discounted price through a different site: xavixstore.com. That site was offered for sale on January 15, 2015, and was no longer supported by SSD.

Xbox. See Microsoft Xbox

Xbox Game Studios

Xbox Game Studios is a division of Microsoft that produces games for the line of Microsoft Xbox console systems. The company was previously known as Microsoft Games (2000), Microsoft Game Studios (2001–11), and Microsoft Studios (2011–19), and as of 2019, it was the parent organization of fifteen game development studios. The company also owns the *Age of Empires*, *Gears of War*, *Halo*, *Minecraft*, *Microsoft Flight Simulator*, and *State of Decay* franchises.

Microsoft Games began in 2000 and was formed from an internal games group at Microsoft that made games for Microsoft Windows. It was formed around the same time that the Microsoft Xbox home console system was announced, and it began to develop games for the console. Microsoft Games first acquired Bungie during the time the studio was working on *Halo: Combat Evolved* (2001), which became an Xbox exclusive game. In 2001, Turn 10 Studios was started for the *Forza* series of racing games, and that same year, Microsoft Games was renamed Microsoft Game Studios.

In 2002, Microsoft Game Studios acquired Rare, which had been founded in 1985 and was known for making games

for Nintendo, and in 2004, it started Carbonated Games for the making of casual games. Microsoft Game Studios acquired Peter Molyneux's Lionhead Studios in 2006 (it would be closed ten years later), and in 2007, Bungie left Microsoft to become a privately held company again. Bungie would continue to make *Halo* games for Microsoft, but the latter company owned the franchise. Microsoft would later start 343 Games to work on further *Halo* titles.

In 2008, Carbonated Games was closed, and Xbox Live Productions was announced as a new studio. In 2009, the company acquired Canadian studio Big Park, and in 2010, it established MGS Mobile Gaming to produce mobile games.

Microsoft Game Studios was renamed Microsoft Studios in 2011, and it acquired Twisted Pixel Games that same year and developer Press Play in 2012. Twisted Pixel would later leave Microsoft in the fall of 2015, and Press Play would be closed in 2016. In 2014, Microsoft Studios bought several franchises, including the *Gears of Wars* series, the *Rise of Nations* series, and the *Rise of Legends* series, and it also bought the Stockholm-based developer Mojang, along with its popular *Minecraft* franchise, for \$2.5 billion.

Microsoft Studios continued buying studios in 2018, acquiring Compulsion Games, Ninja Theory, Playground Games, Undead Labs, Obsidian Entertainment, and inXile Entertainment and, in 2019, the studio Double Fine. Finally, on February 5, 2019, Microsoft Studios was rebranded as Xbox Game Studios to emphasize the console line and its games and other supported devices.

With the continuing support of software giant Microsoft and, as of 2019,

being the only major home console system from an American company, Xbox Game Studios seems well positioned to be a major player in the video game industry into the future.

Xiaobawang System

The Xiaobawang system is a computer-learning machine that offers a combination of functions, including typewriter, game console, and personal computer. The technology for the system's early model, which was called the "Red-White Console" in China, was actually cloned from the Nintendo Famicom (later renamed the Nintendo Entertainment System [NES] for its North American release). Many people from the generation that grew up in China during the

1980s and 1990s have fond memories of playing *Super Mario Bros.* (1985), *Contra* (1987), and *Double Dragon* (1987) using this system.

The early model of the Xiaobawang system had yellow cartridges that contained between forty and one hundred well-known games from Japan and the United States. Compared to gaming consoles from Japan, prices for the system were within the affordable range of ¥100–¥500. In addition to its word processor and keyboard, which allowed children to practice typing in both Chinese- and English-language scripts, the Xiaobawang system functioned as a calculator, message board, and music keyboard, which allowed easy coding, computer chatting, and music composition.

An overview history of the Xiaobawang system's development reveals the beginning of gaming culture in China before the 2000s. Branding itself as an educational technology company, the company Xiaobawang (also called Subor) strived to develop during an era of political reform that called for opening the country's internal market. The company received its license approval from the State Administration for Industry and Commerce. In 1987, its founders created Xiaobawang under its initial name, the Fuzhou Waixing Computer Science and Technology Company. At that time, the country's high price barrier and restrictive import regulations prevented franchised Japanese games and electronics from gaining access to the Chinese market.

Such a business environment benefited the market growth of domestic firms like Xiaobawang, which used the opportunity to successfully distribute its system

widely using celebrity promotion through public media channels. One notable example is Jackie Chan's advertisement endorsement, which appeared on China's most authoritative media channel, China Central Television (CCTV). By 1991, Xiaobawang had become the number one video game manufacturer in China. Sales of its system amounted to 70 percent of the national market. By 1994, its revenue had grown to four billion Renminbi (Beijing News 2018).

However, by the late 1990s, growing parental concern began to pose a challenge to the company and its popular system, as the voice of growing parental concern in Chinese society began to characterize gaming as electronic heroin for schoolchildren. The Ministry of Culture announced it would enforce the government Game Machines Sales Ban in June 2000. The law put an official prohibition on the sale, import, and manufacture of gaming consoles. In response, the company was compelled to stop its operation of the Xiaobawang gaming business. The sales of the Xiaobawang system declined, and the company diverted its production focus to other areas of industry, such as personal computers, audiovisual appliances, home electronics, cell phones, and tablets (Xiaobawang 2019).

The Xiaobawang system has evolved over its twenty years of existence into a variety of models, such as the SB-218, SB-286, SB-486D, SB-926, and SB-986, which reveals a continuous progression from the original Famicom game console to personal computers and other new technologies. In 2016, the Chinese government, which had lifted its ban on consoles, inspired Xiaobawang to return to China's gaming market. In response, in 2018, the company introduced a new

model, the Z+ New Gaming Computer. In this recent comeback, developers of the Xiaobawang system have focused on creating a gaming environment compatible to Windows 10 and virtual reality (VR) technology. The transformation is expected to shift Xiaobawang's development focus to a system that allows the company to compete in the high-end gaming products market, which demands high-quality visuals and improved product design. This expanded range will make it possible for Xiaobawang gamers to play esports titles such as *Defense of the Ancients* (2003) and *PlayerUnknown's Battlegrounds* (2017). The company also collaborates with Sony and independent Chinese game developers to publish copyrighted titles, including *Double Dragon IV* (2017), *On Rush* (2018), and *Bloody Spell* (2019).

XNA

Microsoft XNA is a software platform used to ease the development of video games for the Microsoft Xbox 360 and other Microsoft platforms; however, the

company discontinued support for XNA in 2013 as Microsoft transitioned and replaced development tools in preparation for Windows 8 and Xbox One. XNA provides a set of tools, services, and resources designed to help simplify game creation for professional, student, and hobbyist developers. XNA is typically used to refer to several elements: the XNA Framework, XNA Game Studio, and the XNA development community. XNA was announced in 2004 at the Game Developers Conference (GDC) and was released at the 2006 GDC. XNA is a recursive acronym, standing for "XNA's Not Acronymed."

XNA marks a deviation from historically restricted development for other game consoles, which have typically required developers to buy more expensive development console systems and specialized tools directly from the console manufacturer. In contrast, XNA developers may test their games on retail consoles.

The production of unofficial content for a console system is often prohibited by the console manufacturer, which seeks to regulate content and license game production to share in a game's potential profits. Such noncommercial games for console and handheld systems are called *homebrew games*, and although consumers have produced such content for other console systems, XNA is the first homebrew development platform sanctioned by a console developer.

The XNA Framework is a software development kit (SDK), which is a collection of programming elements for routine functionality that can be combined to make more complex programs. For instance, XNA streamlines the processes for displaying graphics on the screen,

playing sounds, and performing other commonplace game functions. In this way, XNA functions as an application programming interface (API), serving as a software framework to facilitate and speed game development by simplifying the software code in which the games are written. Programs in the XNA Framework are primarily written using Microsoft's XNA Game Studio software using the C# language.

The XNA Game Studio software is a development environment specifically designed for the creation of XNA content built on top of Microsoft's Visual Studio development environment. The first version, XNA Game Studio Express, was made available in 2006, with XNA Game Studio 2.0 released in 2007 and subsequent versions similarly titled. The company operated XNA Creators Club Online, an official XNA community website, through which XNA developers submitted and shared their own games and played and reviewed the games of other XNA content creators. Microsoft ensured that games made with XNA could be easily ported between multiple Microsoft platforms, and game creators could sell their games for the Xbox 360 via the Xbox Live Indie Games service.

Microsoft's robust community support for XNA paved the way for its ongoing legacy as developers active in the XNA

community built upon XNA. After Microsoft announced its discontinuation of support for XNA in 2013, developers continued to use XNA and adapted it to new frameworks and tools for game development. One notable example is the open-source MonoGame, a C# implementation of the XNA 4 Framework, which allows developers to design games in a single environment. MonoGame facilitates readily porting games to multiple platforms beyond Microsoft's, including Android, iOS, MacOS, and consoles such as PlayStation 4, the Nintendo Switch, and Xbox One.

Y

Yokoi, Gunpei (1941–97)

Born September 10, 1941, Gunpei Yokoi was one of the architects of Nintendo's dominant position within the video game industry during the late 1980s and early 1990s. He is most frequently associated with the creation of both the company's seminal handheld gaming device, the Nintendo Game Boy, and of one of its flagship game franchises, *Metroid*.

Upon his graduation from Doshisha University in 1965 with a degree in electronics, Yokoi took a position at the then toy manufacturer, where he would devise numerous mechanical toys, tools, and novelties before creating Nintendo's first handheld video game device in 1980, the Game & Watch LCD game. Conceived as a low-cost alternative to direct competition with dominant console manufacturers such as Atari and Mattel, more than sixty Game & Watch models were produced over the following decade, a period that also saw the 1983 debut of Nintendo's Famicom (rechristened the Nintendo Entertainment System [NES] for its 1985 Western release). The console was designed by Masayuki Uemura, a personal hire of Yokoi's, who himself developed a successful peripheral for the NES, the Robotic Operating Buddy, or R.O.B. The appeal of Yokoi's device helped assuage American consumers' skepticism in a new video game console following the industry crash of 1983. Yokoi would also personally spearhead the development of two of the NES's

most beloved games, *Metroid* (1986) and *Kid Icarus* (1987), as producer.

With Nintendo's place in the home console market firmly secured, Yokoi's most famous creation, the Game Boy, would ensure the company's dominance in the handheld sector for decades to come. Released in 1989, the Game Boy boasted a two-inch monochrome screen and mono audio. It could be played for up to thirty-five hours on four AA batteries and was sold bundled with Alexey Pajitnov's addictive puzzle game, *Tetris* (1985). This sensation, along with Yokoi's own handheld iteration of Nintendo's flagship character, *Super Mario Land* (1989), drove sales of the original Game Boy to more than fifty million units. Yokoi would develop two *Mario Land* sequels, *Super Mario Land 2: Six Golden Coins* (1992) and *Wario Land: Super Mario Land 3* (1994), for the Game Boy as well as a sequel to his second most famous creation, *Metroid II: Return of Samus* (1991).

Super Metroid, widely revered for its evocation of mood and place, followed on the Super Nintendo Entertainment System (SNES) in 1994. In 1995, however, Yokoi's next invention, the ill-fated Nintendo Virtual Boy, was widely regarded as a colossal failure. The device's stand-mounted visor design and red monochrome screens prompted complaints of physical discomfort among the gaming press and complete indifference from the buying public. With the majority of Nintendo's resources focused on the 1996

Two of Yokoi's most enduring creations: bounty hunter Samus Aran appears in Yokoi's *Metroid II: Return of Samus* (1991) for the Nintendo Game Boy, which was also designed by Yokoi. (Courtesy of Mark J. P. Wolf)

launch of the Nintendo 64, the Virtual Boy became an embarrassment to Yokoi, and he left the company later the same year. Forming a new company under the name Koto Laboratory, Yokoi began work on a new handheld device that would ultimately be released in 1999 as Bandai's WonderSwan.

Tragically, Yokoi would not live to see the WonderSwan's completion. On October 4, 1997, Yokoi and his business associate Etsuo Kiso were struck and killed by a car on Japan's Horukiko Expressway after being involved in a minor collision.

YouTube

YouTube is a video-sharing website that was created in 2005 by Chad Hurley, Steve Chen, and Jawed Karim, three former employees of the online banking

website PayPal. Originally, its purpose was to let anyone upload and share video content easily over the internet as well as integrate it on then budding blogging websites and create communities around this content. After quick early growth, it was bought and expanded on by Google in 2006. Its videos are often published by individuals, though it is also used by companies for promotion or diffusion of content, and the videos can be monetized through the use of advertisements. This business model meant that, over time, the website acted as a real television network, with its stars and recurring series kept afloat by their popularity, though YouTube itself does not contribute to the content directly.

YouTube features have included different platforms divided by type of content (for children, video games, etc.), livestreaming, and paid-for channels in a subscription model. This platform is significant for video game-related content, as these videos and channels are among the most popular on the website, and many different types of content featuring video games have emerged there over time. The popularity of YouTube and its video game-related content has contributed to changes in the marketing of the games themselves, as it became more and more important for developers to have their creations showcased by the website's stars, often dubbed "YouTubers" or "influencers."

Over time and as YouTube grew in popularity, several different genres of video game-related content emerged. Longplays, a video equivalent to text-based walkthroughs, showcase a game from its beginning to its end, often for informational or archival purposes. Their presentation is usually sober, so as

to present a game as purely as possible, without overlaid commentary. Speedruns feature a player attempting to complete a game as fast as possible, and esports videos present entire tournaments or simply highlights of an event or a specific player in competitive gameplay.

Let's Play videos might, however, be the core of YouTube's video game-related content in terms of popularity. For these, the creators tend to take a more active stance, commenting on their performance or critiquing the game as they play. Their purpose can be various, from pure entertainment to showcasing certain games or techniques within them. Another purpose of Let's Play videos might be to put the game in context: to bring the viewer from an incomplete understanding of a game to a more complex and well-rounded one. This content format originated from the forums of an internet community named Something Awful, where game events were made and commented on via text and screenshots. This type of Let's Play video ended up forming a community (the Let's Play Archive) on its own rather than being spread across forum posts; but these were eventually mostly superseded by the video format of YouTube.

As video game-related content became monetized and, for some, a main source of income, several legal issues have emerged over the status of the video game as a creator's platform for expression. These issues echoed other copyright litigation against YouTube throughout the years with television and film conglomerates as well as the online platform's well-known Content ID system. Due to the sheer amount of content uploaded to the website, automation had to be used to ensure that videos complied

with copyright law, which resulted in debates in its community as well as false reports and abuses. Video game content creators, who do not technically own the game content itself, have been the target of game developers and publishers in litigation as well, but it has also been uniquely argued that the video content creators express their creative impulse through the game and that that, by itself, creates entirely new content. The complexity of this issue has left it in a legal gray zone, but monetization and creation of this content has generally been allowed, especially as developers gained benefits from the marketing effect of content creators' popularity—an effect that might have been more easily noticed by a medium more in touch with the internet and new distribution methods.

Finally, this platform has been described as a “cultural archive”—as containing a repertoire of curated content preserved online—both provided by content owners such as labels publishing their own back catalogue and by amateur archivists publishing their collections. This “living archive of contemporary culture from a diverse range of sources” (Burgess and Green 2018, 135–136) extends to video games, with efforts to preserve older games and hardware. Although this medium is a good fit for video games' audiovisual content, it does little to preserve its gameplay. As such, it is not usually seen as an

archive on its own, rather as a tool that can be used by video game historians to preserve at least part of those experiences. However, as much of this content is in the hands of many companies, historians, and archivists, it is also prone to sudden content deletion. Popular video game content channel Machinima, for example, after being bought out, removed years of content from the website, denying public access to it for academics and historians alike. As useful as a resource like YouTube might be, then, it remains unstable and ever shifting, a heritage of its early days as a mostly social endeavor.

Z

Zapak (Portal)

According to the company's website, Zapak Digital Entertainment Ltd. is one of India's largest gaming companies that addresses the complete value chain of digital gaming. With ten million registered gamers, Zapak.com claims to be the largest casual gaming site in the country and among the top casual gaming sites in the world. The company describes itself as the only portal in the world that offers games across all genres: single-player, multiplayer, downloadable games, kids' games, girls' games, and cricket games (a very popular genre in India), among others. The company distributes its games in the United States, Europe, South Africa, Australia, the Middle East, and Asia.

As of 2013, the company announced having passed the 100 million user downloads mark from all of its game titles on the Nokia Store (with over 350 of Zapak's own game titles). At the time, its most popular game was *T20 Cricket 2012* (2012) with 7.76 million downloads. The company is known for games such as *Speedway Racing*, *Stealth Sniper*, and *Super Boxing*. In the summer of 2018, Zapak launched *Little Singham*, a mobile game (free to play on the Google Play Store), which garnered over 3 million downloads and became a top game in India.

Zapak is a unit of Reliance Games, which belongs to Reliance Entertainment. (Reliance Games provides music,

sports, and internet and mobile portals as well as user-generated content, but Reliance Entertainment does not break down its revenues. The company also acquired the U.S. animation studio DreamWorks in 2009.) Zapak was created in 2006 by Venkatarao Ponnada, Shibasish Sarkar, and Amit Khanduja. The following year, it introduced Zapak-mail, a fast e-mail service, but it discontinued the service two years after. In 2010, games were made available on Facebook. In 2011, it launched Zapak Plus, the first subscription-based gaming model in India.

The mother company had consolidated its gaming business in 2012; it was spread across Zapak and Jump Games brands and rebranded as Zapak Mobile Games. As of December 2018, most of its traffic originated from India (nearly 87%) followed curiously by Greece with 6 percent (Alexa 2018). In 2015, the mother company sold off 10 percent of its stake to China-based Lead Eastern Group for \$15 million, creating a three-way joint venture between Reliance Games, Lead Eastern (a publicly listed Chinese company invested in gaming, film, and television production and part of Lead Holding), and Creative Cultural (a Hong Kong firm engaged in intellectual property-based entertainment, including gaming). The deal valued Zapak at \$150 million.

Zapak has a WAP (wireless application protocol) site called m.zapak.com, which is one the world's first multiplayer

platforms for smartphones. It offers over twelve hundred free games and boasts of over two million unique visitors every month. Zapak Games, the licensing and merchandising arm of Zapak, has created one of India's largest retail distribution networks, with presence in over five thousand retail outlets across one hundred cities across India. The company operates high-speed gaming cafés as Zapak GamePlexes. Zapak also launched multiple game zones at Fun Republic malls in Chandigarh, Ahmedabad, Lucknow, and Mumbai.

Zapak has strong content partnerships in the mobile and PC gaming spaces and works closely with most of the leading global gaming and entertainment players, such as Microsoft, PopCap, Boonty, PlayFirst, Universal Studios, Shanda, Cartoon Network, THQ, iPlay, and Hands-On. Backed by the holding company Reliance Entertainment, Zapak seems to be in a good competitive position to benefit from the growth of the Indian gaming market. India is now one of the top five markets for mobile gaming in terms of number of users (Laghate 2018); the expanding smartphone user base and rising internet penetration are the key driving factors for this growth (Simon 2018).

Z-Axis Depth

Video games use techniques found in other graphical media for suggesting depth into the picture plane (i.e., along the z-axis): overlap, apparent size, linear perspective, foreshortening, texture gradients, aerial perspective, shadowing, parallax, and the rotation of objects. The use of these techniques depends on the state of available technology and game design, which determine what can be put into practice.

Early games, with their simple graphics, were unable to achieve much illusion of depth. Overlap and apparent size were used, but the simple shapes and few colors available made it difficult to counter the screen's flatness. Attempts at linear

perspective came in 1976, when racing games such as *Datsun 280 Zzzap* and *Night Driver* both featured small white rectangles arranged to suggest roadside pylons that defined a roadway extending toward a vanishing point. Scalable sprites, introduced in the 1970s, also helped smooth changes in apparent size. Advances during the 1980s, including higher-resolution imagery, texture gradients, and more available colors, increased the amount of graphical detail and made subtler depth cues possible, creating a better illusion of depth in game imagery.

True three-dimensional computation, which rendered views of scenes produced with three-dimensional coordinate systems, first appeared commercially in vector games such as *Speed Freak* (1978), *Barrier* (1978), and *Battlezone* (1980). The first three-dimensional game with filled-polygon graphics was *I, Robot* (1984), but its graphics were simple and abstract; it would not be until the late 1980s that games with three-dimensional filled-polygon graphics would appear regularly.

While games awaited the computing power necessary for true three-dimensional graphics, other design strategies were used to simulate depth. Shifting, overlapping planes could produce a parallax effect, as in *Moon Patrol* (1982). Sprites were detailed enough to allow characters to appear in different positions, making them look more dimensional. Large numbers of sprites could be scaled to produce a three-dimensional feel, as in *Pole Position* (1982) and *Space Harrier* (1985). A few games were 3-D through the use of stereo images, such as *Subroc-3D* (1982). Axonometric projections gave graphics a three-dimensional feel without any three-dimensional

calculations, as in *Q*bert* (1982) and *Crystal Castles* (1983). Images with first-person perspectives were used in *Maze War* (1974) and *Spasim* (1974), and pre-rendered three-dimensional imagery was used in laserdisc games and early CD-ROM-based games. Each of these methods, however, had its limitations, and none of them allowed dynamic, interactive camera movement in real time.

With the advent of true three-dimensional computation done in real time, interactive three-dimensional environments became possible, and the z-axis depth they generated was based on a three-dimensional coordinate system that made their spaces look more realistic. Computer graphics advances such as the z-buffer helped to reduce the amount of processor speed and memory needed to produce imagery with depth, but both still limited what was possible. Sight lines extending too far into the distance made render time too slow for real-time interaction. Thus, games had to limit the amount of depth in the player's view; for example, the first two *Grand Theft Auto* games had an overhead view of the street to limit what needed to be rendered. Other games designed their landscapes or building interiors with limited visibility, so only a small portion of the world can be seen at any given time. Devices such as fog, shadow, and exaggerated aerial perspective obscured visibility beyond a certain distance, as in games of the *Tomb Raider* and *Silent Hill* series. As computing power increased, depth-obscuring devices became less necessary. Methods that reduce render time are still used, however, such as NURBS, nonuniform rational basis (or Bézier) splines, which dynamically reduce an object's polygonal resolution as it moves into the

distance, reducing the number of polygons needed to be rendered.

Z-axis depth is necessary for a strengthened illusion of a real three-dimensional space, and although it places demands on hardware, software, and game design, it fills the player's viewpoint with a larger and more detailed world of interconnected locations, adding to a game's verisimilitude and encouraging player involvement.

Zaxxon

SEGA's *Zaxxon* was released in January 1982 amid a deluge of space-themed shooting games that appeared in the late 1970s and early 1980s. Space battles figured in games from very early on, including *Spacewar!* (1962) and the arcade cabinet games *Computer Space* (1971) and *Galaxy Game* (1971). The very popular *Space Invaders* (1978) was followed by *Galaxian* (1979), *Phoenix* (1980), *Defender* (1981), and *Galaga* (1981), among others. During this period, space shooters were fertile ground for experimentation in game form. *Galaxian*, *Galaga*, and *Phoenix*, for example, featured innovations such as parallax depth effects, variation in enemy behaviors, and, in *Phoenix*, boss battles.

While it integrates many of these innovations, *Zaxxon* is most notable for its

pioneering use of isometric graphics (specifically, a dimetric projection) and shadows to create an illusion of three-dimensional space. In most games before *Zaxxon*, only one plane of each object would be visible. Thus, a spaceship was typically shown from above, as in *Galaxian*, or from the side, as in *Defender*. *Axonometric projection*, the term from which the title *Zaxxon* is derived, describes perspectives in which multiple planes of objects are simultaneously visible. In the variety known as *isometric perspective*, the *x*, *y*, and *z* axes are separated by equal angles, creating an appearance of depth with no horizon line or vanishing point. While technical limitations inhibit true isometric perspective in raster graphics, the term is commonly used for the (technically dimetric) approximations of isometric perspective achieved by games like *Zaxxon*. With its emphasis on schematic proportionality over diegetic verisimilitude, isometric perspective has ultimately proved more popular for strategy games such as *Populous* (1989) than it has for action games.

Players of *Zaxxon* control the position, but not the velocity, of a colorful spaceship as it negotiates an indefinitely repeating level structure. The ship first infiltrates an airstrip that seems to be installed on a floating space rock. The primary challenge of this stage is avoiding objects and walls while traversing the airstrip. In this respect, the game's isometric perspective becomes a challenge in itself, as it can be difficult to judge altitude without a vanishing point; to compensate, *Zaxxon* provides an altimeter at screen left and a shadow that expands as the ship's altitude decreases. The second phase of each level depicts space combat against advancing waves of enemy ships,

which can themselves move up and down as well as left to right in game space. Finally, the ship infiltrates a fortress and does battle against a giant robot. When the robot retreats or is destroyed, the process repeats.

Zaxxon was very popular at the time of its release, owing in part to an unprecedented television campaign for an arcade game, and it was ported to a number of home consoles. Perhaps most notably, a SEGA Master System port of the game continued *Zaxxon*'s experimentation with optical perspective, trading isometric projection for vanishing point perspective, compatible with the Master System's stereoscopic 3-D glasses peripheral.

Zeebo

The Zeebo is a 3G-enabled game console that was introduced in Brazil and Mexico in 2009. The development of the

Zeebo console began as a partnership between California-based Qualcomm and Brazil-based Tectoy. Executives that included Reinaldo Normand, Mike Yuen, and John Rizzo oversaw the initial launch of the console at the Game Developers Conference (GDC) in San Francisco in March 2009. Initial tech press and blog accounts called the Zeebo the console for the "next billion" gamers.

The original impetus behind the Zeebo console was Reinaldo Normand's desire to create a console that would be affordable for middle-class families in emerging markets (Hall 2009). Zeebo pursued partnerships with local wireless carriers, such as Claro, using a 3G connection bundled with the console as a way to distribute games digitally, avoiding distribution problems posed by the geographic limits of broadband infrastructures. Zeebo's corporate leaders also considered digital distribution via 3G networks as a way to curtail rampant piracy. Games were released in BREW (binary runtime environment for wireless), which led some critics and players to argue that the Zeebo was not a game console in the traditional sense but a glorified cell phone.

Because of lackluster sales and problems in establishing game markets in Latin American markets, the Zeebo has recently been repositioned as an educational platform. Part of the failure of the Zeebo may be due to the fact that major game publishers and developers used the system to port titles and as a way to monetize back catalog titles. Although the system was more affordable than legal versions of current consoles, it was only slightly cheaper than pirated versions of the Microsoft Xbox 360 and the Sony

PlayStation 3 that allowed game players to access current titles (also available on the black market). Despite problems with the console, independent developers and Latin American developers expressed enthusiasm over the emergence of a new platform that might allow them new forms of access to consumers—unlike the licensing arrangements and complicated approval processes associated with the big three consoles and the Apple iPhone.

Corporate restructuring has shifted the Zeebo from being a game console designed for entertainment to a platform designed to improve educational access and literacy; however, the Zeebo's introduction as a new console illustrates the need to develop more nuanced accounts of cultural differences in gameplay and how transnational and global accounts of gaming industries and cultures must move beyond a focus on the big three markets of the United States, Japan, and Europe.

Zelda Series. See *Legend of Zelda, The Series*

Zen Mode

Although some uses of Zen terminology and imagery can be found in twentieth-century games, such as *Monty Python's the Meaning of Life* (1997), self-titled "Zen Modes" became common during the casual revolution of the first decade of the twenty-first century. Early examples of this are PopCap games such as *Chuzzle* (2005) and *Bejeweled Twist* (2008), which included Zen Modes that removed scores, time limits, and other obstacles to create a "stress-free" experience. Later games, such as *Fruit Ninja* (2010) and *Dexed* (2017), have used the concept in a similar way.

Since their inception, Zen Modes have been regularly associated with reinterpretations of the ideas of immersion and flow. Jenova Chen's *fLOW* (2006), a precursor of *Flower* (2009) and so-called Zen gaming, was created as part of a master's thesis on flow. The complete removal of loss conditions is thus a defining trait of these modes. With this, challenge and difficulty, together with their demands and motivations, give way to experiences closer to meditation and relaxation, often in endless play structures.

Zen Modes are usually connected to the Western perception of Zen as a minimalist aesthetic, defined by simplicity and austerity. Zen Modes like those in *Alto's Adventure* (2015) or *Bejeweled 3* (2010) modify their game's presentation, changing the soundtrack to a more serene and calming one or allowing the player to activate ambient sounds, breathing instructions, and binaural beats.

Some games have used this aesthetic as a central element of their design, beyond a specific mode, in a style or genre defined by their creators and marketers as “Zen gaming.” This is the case of pioneers such as *Flower*, *Osmos* (2009), and *Zen Bound* (2009). *Tetris Effect* (2018) includes numerous Zen motifs to accompany its focus on trance and synesthetic visuals. *Abzû* (2016), a game heavily influenced by the “Zen game” *Journey* (2012), features “meditation rocks,” where the player can use a “meditate” mechanic that results in an achievement called “Zen Master.”

Other Zen games and Zen minigames exploit sitting meditation, or Zazen, to make the player sit down as an input, either as an actual Zazen instruction tool or for playful purposes. In the first category we find the Kinect apps *Zazen* (2017) and *Deepak Chopra’s Leela* (2011), whereas the second one includes games such as *Wii Fit* (2007), played using the Wii’s Balance Board, the “Zen” minigame in *1 2 Switch* (2017), and *Guru Meditation* (2008).

Very often, Zen Modes are reductions, misinterpretations, or, in the worst case, commodifications of Zen ideas, practices, and iconography. They adhere to popular trends in the West that present relaxation and well-being as their ultimate goals and Zen-like elements as goods that help the consumer achieve that well-being. Many Zen Modes, like colorable mandalas and certain mindfulness programs, fit in what some have labeled “McMindfulness” trends and bear no relation to actual Zen play practices such as Go, haiku competitions, or kôans.

Zynga Inc.

Zynga Inc. is an American video game developer based in San Francisco, California. The company was a pioneer in the genre of social games, and for much of its history, it has remained a market leader in browser-based and mobile games.

The company was founded in 2007 by Mark Pincus, Justin Waldron, Eric Schiermeyer, Michael Luxton, and Steve Schoettler, and it was named after Pincus’s American bulldog, Zinga. Under Pincus’s management, Zynga utilized Facebook to reach vast numbers of users and reap massive profits. According to estimates, Zynga had an active base of over forty million players by 2009 for titles such as *Zynga Poker* (2007), *Mafia Wars* (2008), and the lucrative *FarmVille* (2009).

Zynga’s products popularized the free-mium model for games, allowing most

The Zynga sign and bulldog logo on the facade of the social video game services company building. (Michael Vi/Dreamstime.com)

users to play for no charge while offering decorative items, power-ups, and short-cuts for cash sales. The model proved successful, and by 2011, Zynga accounted for 19 percent of the revenue moving through Facebook. The company was valued at \$10 billion in an IPO (initial public offering) in December of that year.

In 2010, the company moved into a massive 668,000-square-foot facility in San Francisco, offering amenities to employees like daily complimentary gourmet meals, an on-site dog park, a wellness center, and other plush Silicon Valley perks. But Zynga's corporate culture carried a reputation as a harsh meritocracy. Isolated development teams were routinely put into competition with one another for resources and sales goals, management scoured metrics to identify and cull weak links on their teams, and

employees complained of long hours and unrealistic deadlines.

These problems were often credited directly to Pincus himself. Pincus frequently drew controversy, including a speech in which he admitted to unscrupulous business tactics in pursuit of profit and an incident in which Pincus threatened to fire a number of long-term employees if they did not agree to abandon their unvested stock before the IPO.

Pincus also faced questions over his company's design strategies. Zynga faced persistent allegations that their most popular titles were only slightly altered versions of existing games, including such heavyweight titles as *FarmVille*, *Mafia Wars*, *Café World* (2009), and *Dream Heights* (2012). These issues did little to endear Zynga to the rest of the industry or settle questions about whether Zynga's

skill-light products qualified as games or profit-hungry scams.

Zynga suffered heavy losses when user trends shifted away from Facebook. Facebook accounted for 86 percent of Zynga's business in 2012. After the failure of its own browser-based platform, and unable to pivot to mobile as quickly as smaller competitors, Zynga lost market share rapidly from 2012 to 2014, resulting in layoffs. Pincus left his role as CEO in 2013, causing stock prices to rise; briefly returned in 2015; and then seemingly stepped down for good in 2016. He remains chairman of the company's

board. Although not able to regain their previous heights, Zynga's shift to real-money gambling games and mobile gaming has stabilized the company. More recently, Zynga entered into licensed games, with *Willy Wonka Slots Vegas Casino* (2016) and *Willy Wonka's Sweet Adventure* (2018).

EDITOR

Mark J. P. Wolf is a professor in the Communication Department at Concordia University Wisconsin. He has a BA (1990) in Film Production and an MA (1992) and PhD (1995) in Critical Studies from the School of Cinema/Television (now renamed the School of Cinematic Arts) at the University of Southern California. His books include *Abstracting Reality: Art, Communication, and Cognition in the Digital Age* (2000); *The Medium of the Video Game* (2001); *Virtual Morality: Morals, Ethics, and New Media* (2003); *The Video Game Theory Reader* (2003); *The Video Game Explosion: A History from PONG to PlayStation and Beyond* (2007); *The Video Game Theory Reader 2* (2008); *Myst and Riven: The World of the D'ni* (2011); *Before the Crash: Early Video Game History* (2012); *Encyclopedia of Video Games: The Culture, Technology, and Art of Gaming* (two-volume first edition, 2012); *Building Imaginary Worlds: The Theory and History of Subcreation* (2012); *The Routledge Companion to Video Game Studies* (2014); *LEGO Studies: Examining the Building Blocks of a Transmedial Phenomenon* (2014); *Video Games around the World* (2015); *Video Games and Gaming Cultures* (four volumes, 2016); *Revisiting Imaginary*

Worlds: A Subcreation Studies Anthology (2017); *Video Games FAQ* (2017); *The World of Mister Rogers' Neighborhood* (2017); *The Routledge Companion to Imaginary Worlds* (2017); *The Routledge Companion to Media Technology and Obsolescence* (2018); *101 Enigmatic Puzzles: Fractal Mazes, Quantum Chess, Anagram Sudoku, and More* (2020); *World-Builders on World-Building: An Exploration of Subcreation* (2020); *Exploring Imaginary Worlds: Essays on Media, Structure, and Subcreation* (2020); and two novels for which he is looking for a publisher.

He is also founder and coeditor of the Landmark Video Game book series, the founder and editor of the Imaginary Worlds book series, and the founder of the Video Game Studies Scholarly Interest Group and the Transmedia Studies Special Interest Group within the Society of Cinema and Media Studies. He has been invited to speak in North America, South America, Europe, Asia, and Second Life; has had work published in journals, including *Compar(a)ison*, *Convergence*, *Film Quarterly*, *Games and Culture*, *New Review of Film and Television Studies*, *Projections*, and *The Velvet Light Trap*; is on the advisory boards of Videotopia, the International Arcade Museum

Library, and the *International Journal of Gaming and Computer-Mediated Simulations*; and is on several editorial boards, including those of *Games and Culture* and the *Journal of E-Media Studies*. He lives in Wisconsin with his wife, Diane, and his sons, Michael, Christian, and Francis. [mark.wolf@cuw.edu]

CONTRIBUTORS

Espen Aarseth is principal researcher at the Center for Computer Games Research, IT University of Copenhagen. From 1996, Aarseth was an associate professor and, from 2002, a professor at the Department of Humanistic Informatics at the University of Bergen, which he cofounded. He holds a cand. philol. in comparative literature and a Dr. Art. in humanistic informatics, both from the University of Bergen. He has published research on digital power and democracy, science fiction and cyberpunk, digital media, digital literature, humanistic informatics, games and narrative, women and gaming, game ontology, games and cross media, game addiction, and mobile games. He is also cofounder and editor in chief of the journal *Game Studies*, founder of the Digital Arts and Culture conference series, and cofounder of the following conferences: Philosophy of Computer Games, the History of Games, and Games and Literary Theory as well as author of *Cybertext: Perspectives on Ergodic Literature* (1997), a comparative media theory of games and other aesthetic forms. [aarseth@itu.dk]

César Albarrán-Torres is a senior lecturer in media and communication. He has been widely published in academic and nonacademic titles as a film and literary critic, author, and translator. His current research

focuses on what he calls *gamble-play media*, hybrid platforms where gambling and digital interactive media intersect. His other research interests include film and television as well as the negotiations between social media and politics in Mexico, particularly concerning the drug cartels. He is the author of *Digital Gambling: Theorizing Gamble-Play Media* (2018). [albarran.cesar@gmail.com]

Frederick Luis Aldama is Distinguished University Professor, Arts & Humanities Distinguished Professor of English, University Distinguished Scholar, and Alumni Distinguished Teacher at the Ohio State University. He is the 2018 recipient of the Rodica C. Botoman Award for Distinguished Teaching and Mentoring and the Susan M. Hartmann Mentoring and Leadership Award. He is the award-winning author, coauthor, and editor of forty books. In 2018, *Latinx Superheroes in Mainstream Comics* (2017) won the International Latino Book Award and the Eisner Award for Best Scholarly Work. He is editor and coeditor of eight academic press book series as well as editor of Latinographix, a trade-press series that publishes Latinx graphic fiction and nonfiction. He is creator of the first documentary on the history of Latinx superheroes in comics (Amazon Prime) and cofounder and director of SÕL-CON: Brown & Black Comix Expo. He is founder and director of the Obama White House award-winning LASER: Latinx Space for Enrichment & Research as well as founder and codirector of the Humanities & Cognitive Sciences High School Summer Institute. He has a joint appointment in Spanish and Portuguese as well as faculty affiliation in film studies and the Center for Cognitive and Brain Sciences. He is the author of a children's book, *The Adventures of*

Chupacabra Charlie (2020). For more on Aldama, visit <https://professorlatinx.osu.edu/>. [aldama.1@osu.edu]

Jessica Aldred is a doctoral candidate and researcher with the Hypertext and Hypermedia Lab at Carleton University in Ottawa, Canada. Her research focuses on digital character animation and the growing intersections between cinema and video games in the age of media convergence. Her work has been published in *Animation: An Interdisciplinary Journal*; *Games and Culture*; and *Mediascape*. [jessica.alred@gmail.com]

Lynn Rosalina Gama Alves has a degree in education from the Faculty of Education of Bahia (1985) and a master's (1998) and PhD (2004) in education from the Federal University of Bahia. Her postdoctorate was in the area of electronic games and learning from the Università degli Studi di Torino, Italy. She is currently a professor and researcher at Bahia's Federal University in Salvador, Brazil. She has experience in education, research on gaming, interactivity, and digital culture. She coordinates research and development projects in digital games, such as *Triad* (FINEP/FAPESB/UNEB), *Buzios: Echoes of Freedom* (FAPESB), *Forest Guardians* (CNPq), *Brazil 2014: Towards the Hexa* (SEC-Ba), *Games Studies* (FAPESB), and *Gamebook Forest Guardians* (Capes, CNPq, Fapesb e Uneb), among others. The productions of the research group are available at www.comunidadesvirtuais.pro.br. [lynnalves@gmail.com]

Aubrey Anable is an assistant professor of film studies in the School for Studies in Art and Culture at Carleton University in Ottawa. Her book *Playing with Feelings: Video Games and Affect* (2018) provides

an account of how video games compel us to play and why they constitute a contemporary structure of feeling that has emerged alongside the last sixty years of computerized living. [aubrey.anable@carleton.ca]

Kara Lynn Andersen is an independent screen studies scholar. Her publications include "My Stockings. Lip Them: Consuming Japan through Film and Video Games" (*Post Script Special Issue: Japanese Popular Culture in Films*, Spring/Winter 2009) and "Harry Potter and the Susceptible Child Audience" (*CLCWeb: Comparative Literature and Culture*, volume 7.2, 2005). Her research interests include digital cinema, animation, video games, and digital media. [KLAndersen@brooklyn.cuny.edu]

Thomas H. Apperley, PhD, is an ethnographer that specializes in researching digital media technologies. His previous writings have covered broadband policy, digital games, digital literacies and pedagogies, mobile media, and social inclusion. Tom is currently a senior lecturer at UNSW Australia (the University of New South Wales). He is the editor of the open-access peer-reviewed journal *Digital Culture & Education*, and his open-access print-on-demand book *Gaming Rhythms: Play and Counterplay from the Situated to the Global* was published by the Institute of Network Cultures in 2010. His more recent work has appeared in the journals *Digital Creativity*, *First Monday*, and *Westminster Papers in Culture and Communication*. [thomas.apperley@gmail.com]

Rhino Ariefiansyah is a junior lecturer and researcher at the Department of Anthropology, Universitas Indonesia. He received his bachelor's degree in cultural

anthropology from Universitas Indonesia in 2003 and graduated from the master's program in experimentation in art and politics (SPEAP) from SciencesPo, Paris, in 2014. His research interests are the topics of human ecology, migrations, and climate change. Since 2006, he has been exploring different means of audiovisual media as part of his ethnographic research. He has produced several ethnographic videos, including *Bisa Dewek* (2006), *Wereng di Sawah Petani* (2011), *Alea* (2014), and *Klub Pengukur Curah Hujan Indramayu* (2015), among others. [rhino.ariefiansyah@gmail.com]

Dominic Arsenault is an associate professor at the Department of Art History and Film Studies of the Université de Montréal and a researcher at the LUDOV lab. His teaching and research are focused on the interactive narrative and writing, history, genre, graphics, and music of video games. In 2017, he published the book *Super Power, Spoony Bards, and Silverware: The Super Nintendo Entertainment System*, and in 2020, he released *Power Up the Chips*, the first chipmetal album for his solo musical project Multi-Memory Controller. [dominic.arsenault@gmail.com]

Ben Aslinger is an associate professor and chair in the Department of English and Media Studies at Bentley University, Waltham, Massachusetts. He is the coeditor of *Gaming Globally: Production, Play, and Place* (2013) and *Locating Emerging Media* (2015). [baslinger@bentley.edu]

Barry Atkins is University of Wales Reader in Computer Games Design at the University of Wales, Newport, United Kingdom. He is author of *More Than a Game: The Computer Game as Fictional Form* (2003) and coeditor, with Tanya Krzywinska, of

Videogame, Player, Text (2007). He has published widely in games and narrative and games and aesthetics. [barry.atkins@newport.ac.uk]

Guillaume Averbuj has been a game designer, project manager, and video game production consultant since 2001 and is currently a scrum master and agility coach in YPF technology and the coordinator of the game design area at Image Campus. He is creator of the Argentine Labor Market of Video Games (IndustriaVG), cofounder and treasurer of the Argentine Video Game Foundation (Fundav), cofounder of the Argentine Video Game Chamber (ADVA), founder and mentor of the GameWorkJam Events Cycle, and creator of the annual networking event for students in Argentina (Networking Jam). [guille.averbuj@gmail.com]

Ralph H. Baer (1922–2014) was an independent engineering consultant and internationally known inventor generally credited with creating the home video game console industry in the 1960s. Baer was an active engineer for over sixty years and accumulated more than 150 U.S. and foreign patents, many of which were in the consumer electronics area and resulted in a variety of products, including many successful electronic toys and games. Typical of these is the SIMON game, an early single-chip microprocessor-controlled game that has been popular for more than thirty years. Baer was the recipient of many professional honors, including the National Medal of Technology, which was presented to him by the president of the United States in 2006; an honorary doctor of laws degree from Pierce Law Center; and many other significant professional awards.

Andrew Baerg is a professor of communication and chair of the Arts & Humanities

Division at the University of Houston–Victoria, Texas. His research interests include sports video games, the relationship between sport and media, and social theory. He has published work on games produced by EA Sports and 2K Sports. He also has an interest in quantification and sports in publishing pieces on analytics, big data, fantasy sports, and neoliberalism. [BaergA@uhv.edu]

Jason Scott Begy is a researcher at the Singapore-MIT GAMBIT Game Lab. His research interests include modes of representation and meaning-making in games—including metaphor, simulation, and semiotics—and the so-called casual games sector. He also teaches game design and manages student game development projects. [jsbegy@MIT.edu]

Matt Benic has worked in game development and related industries for over fifteen years in technical and leadership roles. He has worked on published titles for multiple console and mobile platforms as well as simulation and other applications that make use of game technology. He is currently working on virtual reality training applications for Business Science Corporation in Johannesburg. He has been involved in the budding South African game development community from the start of his career, with an interest in growing the available skills in the country to help the industry level up. [mattbenic@gamil.com]

Tamás Beregi acquired his first computers (a ZX Spectrum and later a Commodore 64) sometime around 1983. He spent the next fifteen years in front of various TVs and monitors playing a wide range of video games and became an adventure game fanatic after playing the first text adventures released by the British company

Magnetic Scrolls in the mid-1980s. Realizing that his childhood had suddenly passed, he quickly started to research game history. His richly illustrated, 450-page book *Pixel Heroes: The First Fifty Years of Computer Games* was published in 2010. It is the first book in Hungarian on the history of video games. Since the early 1990s, Tamás has regularly contributed to leading Hungarian computer and film magazines, where his main interest is the representation of the fantastic and the relationship between video games and movies. In 1999, he founded the first online computer game museum in Hungary.

Tamás first studied biology and geography at university, but his interests later shifted to art history and film studies. He received his PhD in art history from Manchester University in 2008. He is the author of three fantasy novels and wrote a national best seller in Hungary entitled *My One and Onlies* that was later made into a feature film. The book combines Tamás's interest in partying and the underground scene of Budapest with scientific observations on how to find the ideal woman. (The book has a one hundred-page-long appendix that guides the reader through this task with the use of mathematical and geometrical formulas.) Tamás has written scripts for a number of movies, including a romantic comedy, a historical drama, and a Hungarian Icelandic CGI animation movie. He also wrote a successful alternate reality game in 2008. He is currently working for the Hungarian Film Board as a script reader and developer, and he is also adding the finishing touches to his fifth novel. He lives with his cat and dog (both female) in the hills of Buda, where he often goes to collect his favorite mushrooms. [tamas.beregi@gmail.com]

Ophélie Bernard is a master's student, lecturer, and contributor to the research projects at the Montréal center of the UQAT (Université du Québec en Abitibi-Témiscamingue), under the direction of Simon Dor. Her research interests stretch from games to media studies, sociology, and spectatorship in games and queer issues in game studies. The current focus of her studies is on the impact of the games themselves and their gameplay in the spectator experience of video games. [Ophelie.Bernard@uqat.edu]

Courtney Blamey is a PhD student at Concordia University in the Department of Communication Studies. Her doctoral research concentrates on redefining and contextualizing the concept of player agency. Her previous research unpacked Blizzard's approach to community moderation in *Overwatch* (2016) by investigating both developer and community inputs on forums. She is a member of the mLab, a space dedicated to developing innovative methods for studying games and game players. [courtney.blamey@hotmail.com]

Alexis Blanchet is an associate professor in film studies at the Université Paris III Sorbonne Nouvelle, France. Formerly associated with the French National Library and a member of the Observatoire des Mondes Numériques en Sciences Humaines (Omsh), he is currently studying the cultural, economic, and technical synergies between cinema and the video game and is interested in how the public nowadays is being offered extended and transmediatic fictional worlds. [alexis.blanchet@gmail.com]

Wolfgang Boehm is currently a PhD student in the Cinema and Media Studies department at the University of Chicago.

His research focuses on the history and theory of North American animation and the Frankfurt School. He earned his MA in moving image studies from the School of Film, Media & Theatre at Georgia State University. [wboehm1@student.gsu.edu]

Ian Bogost is Ivan Allen College Distinguished Chair in Media Studies and professor of interactive computing at the Georgia Institute of Technology, where he also holds appointments in the School of Architecture and the Scheller College of Business. Bogost is also a founding partner at Persuasive Games LLC, an independent game studio, and a contributing editor at *The Atlantic*. He is author or coauthor of many books, including *Unit Operations: An Approach to Videogame Criticism* (2006), *Persuasive Games: The Expressive Power of Videogames* (2007), *Racing the Beam: The Atari Video Computer System* (2009), *Newsgames: Journalism at Play* (2010), *How to Do Things with Videogames* (2011), and *Play Anything: The Pleasure of Limits, the Uses of Boredom, and the Secret of Games* (2016). Bogost's video games cover topics as varied as airport security, disaffected workers, the petroleum industry, suburban errands, and tort reform. His award-winning games have been played by millions of people, exhibited internationally, and held in institutional collections, including the Smithsonian American Art Museum. [ian.bogost@lcc.gatech.edu]

Nis Bojin is a doctoral candidate at Simon Fraser University's School of Interactive Arts. A designer and writer for *Zeros 2 Heroes Media*, Nis is also the program manager for the National Screen Institute's game writers training program, NSI play-WRITE. With interests in conceptual game design and epistemologies of play, Nis continues to work on various game and

transmedia projects that range from serious games to interactive social networks and alternate reality games. [nisbojin@yahoo.com]

Maude Bonenfant is an associate professor at the Departement of Social and Public Communication, Université du Québec à Montréal (UQAM). She holds a PhD in semiotics and specializes in online social networks and communities, big data and AI, gamification, and video games. She holds a Canada Research Chair on Big Data and Gamer Communities, and she is also codirector of the Research Laboratory for Social Media and Gamification, director of the Homo Ludens research group on gaming practices and communication, and an active member of the research group GRISQ, focusing on information and surveillance in everyday life. [maudebonenfant@hotmail.com]

Jonathan Bonneau teaches in the Communication Department for the University of Quebec in Montreal. He is completing a doctoral thesis on the effect of conflicts in context of role-playing games on the immersion experienced by players. An active member of the research group Homo Ludens and coordinator for the Social Media and Gamification Lab, he orchestrates and supervises multiple research-creation projects exploring artificial and human-machine communication through game design and biometrics. [jobonneau@rocketmail.com]

Aaron D. Boothroyd is a lecturer of new media at the University of Maine. He holds a BA in new media and an MA in interdisciplinary studies. He currently serves as the president of Levelbest LLC, a multimedia studio that specializes in filmmaking and game design. [aaron.boothroyd@maine.edu]

Andrew Borman is the digital games curator at the Strong National Museum of Play in Rochester, New York. He is interested in the game development process with a focus on unreleased and prototype versions of games. His work at the Strong focuses on the preservation of games, including both the preservation of physical games in the museum's collection along with born-digital titles such as those on modern consoles and mobile devices. [aborman@museumofplay.org]

Kelly Boudreau, PhD, is an assistant professor of interactive media theory and design at Harrisburg University of Science and Technology. With a background in sociology, film studies, and games studies, her work focuses on digital games, players, and player communities. Her current research ranges from exploring different forms of sociality in gameplay and player/avatar hybridity developed through the networked process of play to addressing different issues around toxic and problematic behavior in digital gameplay. [kelly.boudreau@gmail.com]

Etienne Brunelle-Leclerc is a PhD student in game studies at Université du Québec en Abitibi-Témiscamingue in Montreal, Canada. His research interests include video game history, strategy game design, and esports. His current work focuses on the latter and seeks to better understand how esports went from a marginal gaming phenomenon to a worldwide cultural industry by untangling the complex and often bilateral relationships between the design and the reception of competitive video games. [etienne.brunelleleclerc@gmail.com]

P. Konrad Budziszewski was a PhD candidate in the Department of Communication and Culture at Indiana University, Bloomington. His research focused on the technologies

of electronic gaming, as reflected in and constituted by the practices, discourses, and affects that surround them.

Nolan Bushnell is an entrepreneur, businessman, and innovator. His career spans over 40 years, during which he has made innovations and contributions to several industries. He is best known as the father of the arcade video game industry (which started with *Computer Space* [1971]) and the founder of Atari, the Chuck E. Cheese entertainment restaurant chain, Axlon (makers of interactive toys), Catalyst (the first high-tech incubator), Etak (the first automobile navigation system), ByVideo (the first online shopping system), and more. Through the years, Bushnell has given more than 2,000 speeches on subjects ranging from his companies, the history of video games, the process of innovation, entrepreneurship, entrepreneurship (bringing to market a new project in an old company), and his ten steps to bringing projects to market with no money. His speeches, although being somewhat irreverent to established clichés, are humorous, high energy, and always thought provoking. Bushnell has been inducted into the *Consumer Electronics*’ Hall of Fame, the Video Game Hall of Fame, and the Computer Museum’s Hall of Fame; he has been named as one of *Newsweek*’s “50 Men That Changed America”; *Restaurant Business*’s “Innovator of the Year”; Distinguished Fellow, University of Utah; and Distinguished Leader of Silicon Valley. His numerous awards include the Amusement Operators of America’s Lifetime Achievement Award; the Agenda “Crystal Ball Award”; the Babson College “Distinguished Entrepreneur” Award; and the British Academy of Film and Television Arts (BAFTA) Lifetime Achievement Award.

Mark Butler, Dr. des., is a cultural scientist, media theoretician, and futurologist. He studied Kulturwissenschaft and European ethnology at the Humboldt University, Berlin, where he also turned in his dissertation entitled *Das Spiel mit sich: Populäre Techniken des Selbst zu Beginn des 21. Jahrhunderts* (*Playing with Oneself: Popular Techniques of the Self at the Beginning of the 21st Century*). Currently, he is a research fellow in the Department for European Media Studies at the University of Potsdam. He has published a monograph and various articles on the psychodynamics, performative aesthetics, and embodied experience of computer game playing. He is also a founding member and editor of the journal *ilinx. Berliner Beiträge zur Kulturwissenschaft* (*ilinx. Berlin Contributions to Cultural Science*). [mark.emerson.butler@googlemail.com]

Kursat Cagiltay is a professor of the Department of Computer Education and Instructional Technology at the Middle East Technical University (METU), Ankara, Turkey. He earned his BS in mathematics and MS in computer engineering from Middle East Technical University. He holds a double PhD in cognitive science and instructional systems technology from Indiana University Bloomington. He is the director of METU’s Audio Visual Systems Research and Development Center and coordinator of the Instructional Technology Support Office. Dr. Cagiltay is the founder of three research groups at METU: Simulations and Games in Education (SIMGE—simge.metu.edu.tr), the HCI research group (hci.metu.edu.tr), and Educational Neuroscience/Neurotechnology (<http://ed-neuro.ceit.metu.edu.tr/en/>). He established Turkey’s first HCI research lab with eye-tracking facility at METU. His research focuses on social and cognitive

issues of electronic games, human-computer interaction, instructional technology, sociocultural aspects of technology, technology-enhanced learning, human performance technology, and educational neuroscience/neurotechnology. [kursat@metu.edu.tr]

Brett Camper designs, studies, and writes about computational media, with a particular interest in media history, games, user interfaces, mapping, and computer graphics technologies. His work as an independent software developer includes 8-Bit NYC, a web map that reenvisions New York in the style of a 1980s video game, and Trees Near You, an iPhone application that maps and tracks more than a half million trees in New York City. He has previously served as the research manager of the Massachusetts Institute of Technology's (MIT's) Education Arcade and is currently the director of product management at Kickstarter, a crowdfunding platform for creative endeavors. He holds an MS in comparative media studies from MIT, where he studied the homebrew community surrounding Nintendo's Game Boy Advance handheld platform. [brettcamper@gmail.com]

Marco Benoît Carbone has a PhD in intercultural studies from the University College London (UCL) and is a lecturer at Brunel University, London, where he teaches modules in the History of Media and Digital Games, Social Research Methods, and Critical Approaches to Design. He is a founding member and the managing editor of *GAME Journal* (www.gamejournal.it) and a member of the editorial board of *JICMS (Journal of Italian Cinema and Media Studies)* from Intellect Publishing. He is a board member of the Italian and British branches of DiGRA

(Digital Games Research Association). His research on games focuses on industries and players in historical and sociocultural perspective and, more broadly, on ethnographic methods and the mediated representations of gender, ethnicity, and nationality. [marcobenoitcarbone@gmail.com]

Marcus Carter is a researcher in digital cultures and human-computer interaction. Building on his undergraduate background in the history and philosophy of science and technology, he completed a PhD in the Interaction Design Lab at the University of Melbourne in 2015, studying the design and player experience of the game *EVE Online* (2003). Dr. Carter has published extensively in game studies on a range of titles, such as *Warhammer 40,000* (1987), *EVE Online*, *Candy Crush Saga* (2012), *DayZ* (2013), and the reality TV series *Survivor* (2000–Present). He is formerly the president of the Digital Games Research Association of Australia and was named one of MCV Pacific's "30 under 30" in the Australian and New Zealand games industry in 2017. Following the completion of his PhD, Dr. Carter was appointed as a research fellow in the Microsoft Research Centre for Social Natural User Interfaces, at the University of Melbourne. In this role, he worked on developing and studying new technologies and interfaces using gaze tracking, conversational interfaces, and touchless gestural interaction, with a focus on their social use and impact. It was in this role that Dr. Carter led the development of the Kinecting with Orangutans project, developing novel digital enrichment for the Orangutans at Melbourne Zoo utilizing the Microsoft Kinect. This has led to his current research interest in how digital technologies can support the animal welfare

and conservation education goals of zoos. Dr. Carter joined the University of Sydney in January 2017. He is currently the degree director for the Master of Digital Communication and Culture and a codirector of the Socio-Tech Futures Lab, exploring the Faculty of Arts and Social Sciences flagship research themes attempting to address the social, ethical, and inclusive challenges with emerging technologies, such as artificial intelligence, robotics, virtual reality, and augmented reality. In 2019, Dr. Carter was included in *The Australian's Research* magazine's list of "Australia's Top 40 Researchers Who Are Less Than 10 Years into Their Careers" and among the top five scholars in Humanities, Arts, and Literature. [marcus.carter@sydney.edu.au]

Sandra Castro Pinzón is a Colombian journalist with a master's in political communication, who uses her knowledge in advocacy to empower the video game industry. She is the founder of Tan Grande y Jugando (TGYJ; which translates to "Grown and Playing"), where she works as a journalist, vlogger, gamer, and researcher. TGYJ is the official organizer of the Women Game Jam Colombia. Castro is currently the video game chapter director of FEDESOFTE, the federation of her country. [scastropinzon@gmail.com]

Francisco E. Cattaneo Esnaola is a graduate of interactive game design at Palermo University, Argentina. He worked on *Blind Ninja* (2019) and *Element Space* (2019) at Sixth Vowel and is currently working on *Quantum League* (2019) at Nimble Giant Entertainment. During November 2018, he assisted the students of game development and transmedia storytelling at Vigo University, Spain, giving his point of view on the game industry and game development. [franfece@gmail.com]

Daniel Cermak-Sassenrath is an associate professor at the ITU, Copenhagen, and member of the Center for Computer Games Research (game.itu.dk) and the Pervasive Interaction Technology Lab (PitLab, pitlab.itu.dk). Daniel is interested in artistic, analytic, explorative, critical, and subversive approaches to and practices of play. More info is available at dace.de. [mail@dace.de]

Humberto Cervera is an entertainment industry professional with eight years of experience in the industry. His video game credits include *Construye tu Mexico* (2012), *El camino para vivir mejor* (2012), *Club VLP* (2012), *Banamex: My Life* (2013), *Robo Jungle Rush* (2013), *Kuijez* (2017), *Mansion Alien* (2019), and *Agent Awesome* (2015), his first original game. In 2015, Humberto started the Original Productions department for Cartoon Network Latin America, in Mexico, where he stayed until 2019. There, he led the development and productions of hit series such as *Villainous* (2017), *Toontorial* (2018), *Viking Tales* (2018), *Frankelda Book of Spooks* (2019), and *The Forgotten Forest* (2019), among other still unannounced projects. He had the honor of also participating on the writing team of *Frankelda Book of Spooks* and *The Forgotten Forest*. Cervera never misses a chance to speak highly of video games and animation, and he is convinced that entertainment can save the world. He has done public speaking at TEDxDF, DevHour, and various universities, such as the ITESM, UIA, and UVM. He currently teaches scriptwriting at ESCENA and Game Design at Platzi. Humberto also has five years of experience as part of the Mexican game press, writing for *Red Bull Mexico*, *IGN Latin America*, and *GoGo Catrina*. Currently, Humberto is once again working as an

independent creator in a variety of projects. His experience as a journalist, an independent creator, and as an executive give him a unique vision for the Latin American entertainment industry. Feel free to hit him up if you want to learn more about the local scene. [Humberto_cervera@hotmail.com]

Peichi Chung, PhD, is an associate professor in the Department of Cultural and Religious Studies, Chinese University of Hong Kong. She teaches courses related to digital culture, global communication, and Asian popular culture. Her research interests are Asian cinema and global game industry studies. Her ongoing publications focus on comparative research of game industry dynamics in East and Southeast Asia. Her present research project examines independent game distribution in China and player welfare in the esports industry in East Asia. [peichichung_1999@yahoo.com]

Karen Collins is Canada Research Chair in Interactive Audio at the University of Waterloo, where she teaches game design and sound for interactive media. She is the author of *Game Sound* (2008) and the editor of a collected volume about interactive audio, *From Pac-Man to Pop Music* (2008). [collinsk@artsservices.uwaterloo.ca]

Mia Consalvo is a professor and Canada Research Chair in Game Studies and Design at Concordia University in Montreal. She is the coauthor of *Real Games: What's Legitimate and What's Not in Contemporary Videogames* (2019) and *Players and Their Pets: Gaming Communities from Beta to Sunset* (2015). She is also coeditor of *Sports Videogames* (2013) and the *Handbook of Internet Studies* (2011) and is the author of *Cheating: Gaining Advantage in Videogames* (2007) as well as *Atari to Zelda: Japan's*

Videogames in Global Context (2016). Mia runs the mLab, a space dedicated to developing innovative methods for studying games and game players. She is a member of the Centre for Technoculture, Art & Games (TAG), and she has presented her work at industry as well as academic conferences, including regular presentations at the Game Developers Conference. She is the past president of the Digital Games Research Association and has held positions at MIT, Ohio University, Chubu University in Japan, and the University of Wisconsin–Milwaukee. [mia.consalvo@concordia.ca]

Patrick Crogan is an associate professor of digital cultures at the University of the West of England. He has published numerous texts on video games in anthologies and journals. He is the author of *Gameplay Mode: War, Simulation and Technoculture* (2011). [Patrick.Crogan@uwe.ac.uk]

Paul Dalg was born in 1986 and studied general history and German philology in Potsdam, Germany. He finished his studies with the BA thesis “Videogames as Threat—Public Discourse and Practices of Youth Protection in the Media in the Federal Republic of Germany (1980–1994).” Between 2011 and 2018, he worked at the German age rating board (USK) as a game tester, online youth protection adviser, and consultant for international video game publishers, and he held talks at GDC Europe and the Quo Vadis Game Developer Conference about youth protection regulation and censorship. Since the end of 2018, Paul has been working as a journalist for games, tech, and digitization at the German newspaper *Der Tagesspiegel* in Berlin. [paul@paulpunkt.de]

Erwan DAVISSEAU is a former video game artist, lead artist, and art production manager who worked thirteen years in the game industry on international renowned franchises such as *Splinter Cell*, *Prince of Persia*, and *Far Cry*. He is a PhD candidate at UQAM (University of Québec in Montréal) and a professor at UQAT (University of Québec in Abitibi-Témiscamingue) in Montréal. His field of research is about video game semiotics and how 3D environments inform the player how to play without the need of overlaid information, such as a heads-up display (HUD). Opposed to the classic way of having two different universes of signs (symbolic versus iconic) to communicate with the player, he argues that a specific genre is developing an effective iconic visual language called ludonarrative resonance by sharing the same universe of signs as the environment (despite its strong complexification and densification over the last decade) to clearly suggest actions to perform. [Erwan.Davisseau@uqat.edu]

Suzanne de Castell is a professor of curriculum and instruction in the Faculty of Education at Simon Fraser University. Her work spans literacy, technology, gender, educational game theory, research, design and development, and multimodal analysis of communicative interaction. Her recent work includes *Worlds in Play: International Perspectives on Digital Games Research* (2008; coedited with Jennifer Jenson), *Loading . . . The Journal of the Canadian Game Studies Association*, work on design and development of educational games (*Contagion* and *A Baroque Adventure*), and recent publications on digital games and education, gender, and gameplay and multimodal learning in informal and community settings. [decaste@sfu.ca]

Mario De Govia has enjoyed video games since the age of six, when his father brought home an Atari 2600. Mario became inextricably linked to the gaming industry when Nintendo co-opted his name and opened the floodgates of playground teasing. After graduating from the University of California, Berkeley, he joined Prima Publishing in 1998 and turned his youthful pain into a career. As an editor, writer, and project manager at Prima, the premier publisher of video game strategy guides, Mario has been involved with some of the biggest titles of the era, from writing the original *Halo: Combat Evolved* (2001) game guide to managing the guides for *Fallout 3* (2008) and *Fallout: New Vegas* (2010). He currently works for KlickNation as a senior director overseeing the Facebook games *Superhero City* (2009) and *Age of Champions* (2010). He does not have a brother named Luigi. [planet4@gmail.com]

Patrick Deslauriers is a PhD student in communication and teaching fellow at the University of Quebec in Montreal (UQAM). The recipient of a Social Sciences and Humanities Research Council (SSHRC) grant, he is a member of the Homo Ludens research group as well as the Interuniversity Center for Research on Communication, Information, and Society (Centre de recherche interuniversitaire sur la communication, l'information et la société, CRI-CIS). He has also worked as a research associate for several video game companies (Behaviour Interactive, Ubisoft, and Vandal Games). His thesis focuses on collective passion and protest dynamics within video game communities. His research interests include communication dynamics and issues within the video game industry and gaming communities. [deslauriers.patrick@uqam.ca]

Jennifer deWinter is a professor of rhetoric and director of the Interactive Media and Game Development program at Worcester Polytechnic Institute. She teaches courses on game studies, game design, and game production and management. Additionally, she teaches in the Professional Writing program. She has published on the convergence of anime, manga, and computer games both in their Japanese contexts and in global markets. Her work has appeared in numerous journals, including *Works and Days*, the *Journal of Gaming and Virtual Worlds*, *Eludamos*, *Computers and Composition*, and *Rhetoric Review*. Additionally, she is the coeditor of the Influential Game Designers book series, for which she wrote a book on Shigeru Miyamoto. [jdewinter@wpi.edu]

Laurie-Mei Ross Dionne is completing a master's degree in anthropology at Université de Montréal, Canada. Her research focuses on Japanese culture and video games and, more specifically, how the genre that has been known as "visual novel" in the West is culturally defined by developers and gamers alike in Japan. She is also an animator, layout artist, and illustrator specialized in 2D animation. [lrossdionne@gmail.com]

Joseph C. DiPietro serves as the Training and Education program manager at the United States Sentencing Commission in Washington, DC. He and his team oversee a variety of education-related courses, deliverables, and professional development resources that help disseminate sentencing-related content for interested parties (typically judges, probation officers, and defense attorneys). Joe is a former public school teacher, instructional designer, and university professor with a passion for all things educational technology related. He has over

sixteen years of experience in managing the planning, delivery, support, and evaluation of online, blended, and face-to-face learning experiences in federal, private sector, post-secondary, and public education environments. Dr. DiPietro is an expert in assessing and promoting the quality of online and blended/hybrid offerings; in maximizing comprehensibility of technology-mediated course structures; and in ensuring alignment between learning objectives and various federal/national accreditation standards. He has vast experience using research- and learner-based needs analyses to engage with and lead colocated or virtual design teams to meet deadline-driven specific learning outcomes. Joe began facilitating online professional development in 2004 and taught his first online course in 2006. He has made mastering his craft the focus of his work, and his areas of interest focus most keenly on the fields of online teaching and learning, best practices of technology-mediated instruction, efficacy of professional development, efficiency in project management, and instructional design innovations. [edug8r@gmail.com]

Tristan Donovan is a British writer and gaming historian. His books include *Replay: The History of Video Games* (2010) and *It's All a Game: The History of Board Games* (2017). He has written about games for *Edge*, *Eurogamer*, *The Times*, *The Guardian*, *Stuff*, *Gamasutra*, and *BBC News* among others. He also writes scripts for the award-winning podcast series *Business Wars*. [tristan.donovan@gmail.com]

Simon Dor is an assistant professor at Université du Québec en Abitibi-Témiscamingue (UQAT). His research mainly focuses on strategy games, whether it is from a gameplay or representational point of view, with a competitive or narrative

lens, or using a cognitive, philosophical, or historical approach. His teaching and research also led him to work on esports, immersion, ethics, emulators, and game design. He also writes on a personal research blog (<http://www.simondor.com>) and often uses Twitch and YouTube to understand their impact on gaming culture and to share his work. [simon.dor@uqat.ca]

Judith Dormans researched narrative fan practices based on pervasive game worlds at Maastricht University, the Netherlands. She graduated from the Digital Games: Theory & Design Master's Program at Brunel University, London. Her research interests focus on communities, narrative, and design in video games. [judithpasmans@gmail.com]

David O. Dowling, PhD, is an associate professor in the School of Journalism and Mass Communication at the University of Iowa. The author of eight books, his most recent is *Immersive Longform Storytelling: Media, Technology, Audience* (2019). His current book project is *Gaming and Journalism: Nonfiction Narrative's Newest Medium*. His research on publishing industries and digital media has appeared in *Convergence*, *Games and Culture*, *Digital Journalism*, *Journalism & Communication Monographs*, and *Genre*, among other journals. He teaches digital and gaming culture, media history and culture, and principles of journalism. [david-dowling@uiowa.edu]

Jon-Paul C. Dyson, PhD, works for the Strong in Rochester, New York, where he is director of the International Center for the History of Electronic Games (ICHEG), vice president for exhibit research and development at the National Museum of Play, and book review editor of the *American Journal of Play*. ICHEG is home to the most

comprehensive public collection of video games and video game–related historical materials in the United States, which are used for scholarly research and the creation of exhibits such as *eGameRevolution*, on display at the National Museum of Play. [jpdyson@thestrong.org]

Trevor Elkington is a popular culture and media scholar. He currently works in cloud software consulting, having previously worked as a producer at Warner Brothers' Surreal Software studio and SCEA's Red-Zone studio. Before working in video game development, Trevor was an assistant professor of popular culture at the University of Copenhagen and has taught literature and media studies at the University of Washington. He is the author of numerous essays on video games, film, and literature. He is coeditor of *Transnational Cinema in a Global North: Nordic Cinema in Transition* (2005), an essay collection that positions the film industries of the five Nordic countries in a globalized context. He received his PhD in comparative literature and critical theory from the University of Washington in 2001. [trevorelkington@hotmail.com]

Barrie Ellis has been building accessible game controllers and pushing for better game accessibility since 1995. He formed the website OneSwitch.org.uk in 2002 to promote one-switch access to leisure and also accessible gaming solutions in general. Since 2007, he has worked with the UK gaming charity SpecialEffect.org.uk, and is currently employed part-time as a technical specialist. He has a particular interest in reduced-control solutions and also the history of game accessibility. From this, a fascinating collection of accessible gaming ephemera has resulted, which he sometimes exhibits and gives talks upon. A related

book, *One Switch 100*, is in the works. [barrie.ellis@oneswitch.org.uk]

Graciela Alicia Esnaola has a PhD in pedagogy and an MA in educational research and teaching quality from the University of Valencia, Spain. She graduated as a specialist in e-learning from the University of Veneto, Italy. She has been a research manager in educative technology and video games and is currently exploring the One Laptop per Child pedagogical model. She has been invited by international universities as an expert in research on video games and learning, and is a professor in the doctoral program at the University of Salamanca and in e-learning courses at the University of Valencia. She coordinates high studies in psychopedagogy and is the author of the book *The Construction of Knowledge in Today's Culture: What Do Videogames Tell Us?* and many scientific publications. Her website is <https://sites.google.com/site/dragracielasnaola/>. [graesnaola@gmail.com]

Anna Everett is a professor of film, television, and new media studies and former chair of the Department of Film and Media Studies at the University of California, Santa Barbara (UCSB). From 2002 to 2005, she was director of the UCSB Center for Black Studies. She has published numerous books and articles, including *Returning the Gaze: A Genealogy of Black Film Criticism, 1909–1949* (2001); *The Revolution Will Be Digitized: Afrocentricity and the Digital Public Sphere* (2001), *New Media: Theories and Practices of Digitextuality* (2003; with John T. Caldwell), *AfroGEEKS: Beyond the Digital Divide* (2006; with Amber T. Wallace), and *Learning Race and Ethnicity: Youth and Digital Media* (2007) for the MacArthur Foundation's new series on Digital Media, Youth, and Learning. Her

monograph *Digital Diaspora: A Race for Cyberspace* won a 2009 Choice Award for Outstanding Academic Book. Among her articles are "The Other Pleasures: The Narrative Function of Race in the Cinema," "The Black Press in the Age of Digital Reproduction: Two Exemplars," "P.C. Youth Violence: 'What's the Internet or Video Gaming Got to Do with It?,'" "Trading Private and Public Spaces @ HGTV and TLS: On New Genre Formations in Transformation TV," and "Serious Play: Playing with Race in Computer Games." Dr. Everett is founding editor of the journal *Screening Noir: A Journal of Film, Video and New Media Culture*. [everett@filmandmedia.ucsb.edu]

Gerald Farca is a professor in game studies and narrative design at the Macromedia University of Applied Sciences in Leipzig. He obtained his PhD in the English Literature department at Augsburg University in 2017, where he is now a member of the Cultural Ecology Research Group (Environmental Humanities). Gerald has published research on game studies, narrative in games, ecocriticism, utopia, dystopia, and science fiction, and he is the author of *Playing Dystopia: Nightmarish Worlds in Video Games and the Player's Aesthetic Response* (2018). In addition, he was a visiting lecturer and researcher at the Center for Computer Games Research at the IT University of Copenhagen in 2016 and the CESAG of the Universidad Pontificia Comillas in Palma in 2018. His research now focuses on ecological science fiction in digital games and the regenerative aspects of play. [gerald.farca@gmail.com]

Febrian was born in Jakarta, February 18, 1986, and has a master's degree in communication science. He graduated in 2014 from Universitas Indonesia. He works for the

Department of Tourism, Vocational Education Program, Universitas Indonesia. [pepi-topepep@gmail.com]

Alexander Fedorov is president of the Russian Association for Film & Media Education since 2003 and vice rector of the Anton Chekhov Taganrog State Pedagogical Institute (Russia) since 2005. He is a member of the Russian Academy of Film Arts & Sciences (since 2002), the Russian Union of Filmmakers (since 1984), CIFEJ (International Center of Films for Children and Young People, Canada), and FIPRESCI. He holds a master's degree from the Russian Institute of Cinematography (VGIK, 1983) and PhD (1986) and EdD (1993) degrees with an emphasis in media education from the Russian Academy of Education (Moscow).

His postdoctoral affiliations include visiting senior research scholar (1998 and 2006) at Central European University, Budapest, Hungary; visiting senior research scholar (2000) at Kassel University, Germany, and at Humboldt University (Berlin, 2005); visiting senior research scholar, 2002 and 2009, at Maison des Sciences de l'Homme (MSH, Paris, France); and research scholar, 2003, at the Kennan Institute (The Woodrow Wilson Center, Washington, DC). He received the scientific grants/fellowships from various institutions, including the Russian Education Ministry (1997–2012); the Russian President Program for Leading Scientific Schools (2003–2005); the MacArthur Foundation (USA), for travel to the UNESCO International Media & Media Education Conference (Paris, France, 1997) and for an individual research project (2003–2004); the Russian Foundation for Humanities (1999–2012); the Cultural Foundation of the President of Russian

Federation (2002); the program Russian Universities in the humanities area (2002); the Soros Foundation (USA); Research Support Scheme (RSS, 2000–2002); the program Civil Society (1998–99); HESP (HESP-CDC—Course Development Competition, 1998); the education program for the best text of university lectures (1997); and the Switzerland Scientific Foundation (2000).

He has been the speaker at many international media and media education/literacy conferences, including the UN “Alliance of Civilizations” (Madrid, 2008); UNESCO Media Literacy Conference (Paris, 2007); Council of Europe Media Literacy Conference (Graz, 2007); Association for Media and Technology in Education, Concordia University (Montreal, Canada, 2003); World Congress “Toys, Games and Media,” University of London, Institute of Education (London, 2002); the Council of Europe’s Hearing on Internet Literacy (Strasbourg, France, March 2002); the 3rd World Summit on Media for Children (Thessaloniki, Greece, 2001); International Council for Educational Media ICEM-CIME—Conference “Pedagogy and Media” (Geneva, Switzerland, 2000); World Summit 2000: Children, Youth and the Media—Beyond the Millennium (Toronto, Canada, 2000); AGORA European Children’s Television Center (Thessaloniki, Greece, 1999); Educating for the Media and the Digital Age (Vienna, Austria, UNESCO, 1999); World Media Education/Literacy Summit (Sao-Paulo, Brazil, 1998); Media & Science (Montreal, Canada, 1997); and Youth and the Media, Tomorrow (Paris, France, UNESCO, 1997).

He is the author of four hundred articles and twenty books about media, film, and media education/literacy. On

September 24, 2019, Fedorov was awarded the Global Media and Information Literacy Award 2019. This award is presented annually, with the participation of UNESCO, for outstanding achievements and leadership in the field of information and media and media culture, to researchers, educators, artists, activists, associations, and other groups that innovatively integrate media and information literacy into their work and related activities. [1954alex@mail.ru]

Richard E. Ferdig is the Summit Professor of learning technologies and professor of educational technology at Kent State University. He works within the Research Center for Educational Technology and the School of Teaching, Learning, and Curriculum Studies. He earned his PhD in educational psychology from Michigan State University. He has served as researcher and instructor at Michigan State University, the University of Florida, the Wyższa Szkoła Pedagogiczna (Krakow, Poland), and the Università degli studi di Modena e Reggio Emilia (Italy). At Kent State University, his research, teaching, and service focus on combining cutting-edge technologies with current pedagogic theory to create innovative learning environments. His research interests include online education, educational games and simulations, the role of faith in technology, and what he labels a deeper psychology of technology. In addition to publishing and presenting nationally and internationally, Ferdig has also been funded to study the impact of emerging technologies, such as K–12 virtual schools. Rick was the founding editor in chief of the *International Journal of Gaming and Computer Mediated Simulations*, and he is the current editor in chief of the *Journal of Technology and Teacher Education*. He

also serves as a consulting editor for the development editorial board of *Educational Technology Research and Development*. [rferdig@gmail.com]

Simon Ferrari is the director of Games and Entertainment Applications at AMC Networks, and he serves on the advisory board for the NYU Game Center Incubator. He is the coauthor of *Newsgames: Journalism at Play* (2010). [chungkingexpress@gmail.com]

Jean-Pierre Flayeux, PhD, is a professor at University of Québec in Abitibi-Témiscamingue, Digital Creation, and New Media (Montreal Center) and is in charge of the Visual Effects program. His research interests include visual effects in films and video games, compositing, rendering and real-time rendering, and artificial intelligence linked to images in movement via Deep Dream (deepflow, deepmatching, style transfer, etc.). He is a member of the Visual Effects Society. He used to work in the game and visual effects industries (Ubisoft, Behavior, Digital Dimension, and Hybride Technologies, among others) for about twenty years before switching to the university. There is more information on his work in film on IMDB :<http://www.imdb.com/name/nm2458331>. [Jean-Pierre.Flaxey@uqat.ca]

Alberto Flores del Río is a screenwriter and a freelance critic who resides in Lloret de Mar (Catalonia, Spain). His works about literature, cinema, music, video games, and new media have appeared in Spanish publications such as *El Mundo*, *Go*, *Quimera*, and *HipHopFlash*. He is currently developing Ludognosis, a multimedia project about video games, semiotics, and audiovisual arts. [floresgohome@gmail.com]

Eelke Folmer is a professor in the Department of Computer Science and Engineering, University of Nevada, Reno. He received his PhD in software engineering from the University of Groningen, the Netherlands. His research interests lie in the area of human-computer interaction, specifically researching interfaces for immersive 3D applications, such as video games and virtual worlds. His current research interests involve virtual locomotion and VR sickness. [efolmer@unr.edu]

Gonzalo Frasca, PhD, is cofounder of Powerful Robot Games, one of the leading game development studios in South America. He is also chair of videogames at the ORT University in Montevideo, Uruguay. As a researcher, his work focuses on game rhetoric, game design, and serious games. Frasca received a Lifetime Achievement Award from the Knight Foundation for his Newsgaming.com project. He also codeveloped the first official video game for a U.S. presidential campaign. [frasca@DragonBox.com]

Gundolf S. Freyermuth is a professor of media and game studies and founding director of the Cologne Game Lab at TH Koeln—University of Technology, Arts and Sciences, as well as professor of comparative media studies at the IFS international film school of Cologne. He earned his MA and PhD in comparative literature from the Free University of Berlin. His research concentrates on the history and theory of audiovisual media, particularly film and games, as well as analog and digital textuality and network culture. Gundolf has written and edited more than twenty books of fiction and nonfiction in English and German and published several hundred articles and papers. His most recent English books are *Playing Utopia: Futures in Digital Games*

(2019, coedited); *Clash of Realities 2015/16: On the Art, Technology, and Theory of Digital Games. Proceedings of the 6th and 7th Conference* (2017, coedited); *Games / Game Design / Game Studies. An Introduction* (2015). [g@freyermuth.com]

Melanie Fritsch is a ludomusicologist and game studies scholar. Her doctoral thesis, *Performing Bytes: Musikperformances der Computerspielkultur (Performing Bytes: Music Performances of Video Game Culture)*, was published in 2018, and she is currently working on the *Cambridge Companion to Video Game Music* in collaboration with Tim Summers. She is a member of the Ludomusicology Research Group (www.ludomusicology.org) and coeditor of the Studies in Game Sound and Music book series (with Intellect Publishing). Further, she cofounded the Society for the Study of Sound and Music in Games (www.sssmg.org) and the *Journal of Sound and Music in Games* (published with University of California Press), is a member (since 2019) of the editorial board of the *Journal of the Royal Musical Association*, and has been co-organizer of the GameCamp Berlin (www.gamecamp.berlin, formerly known as Researching Games BarCamp). She has worked as research assistant at the Research Institute for Music Theatre (University of Bayreuth) between 2008 and 2013 and also taught in its Music Theatre Studies Department (BA/MA). She currently works as a public relations and communications manager in the video game industry, and she also teaches at the Humboldt University of Berlin on a freelance basis. Detailed info on her work can be found at <https://independentresearcher.academia.edu/MelanieFritsch>. [melaniefritsch@arcor.de]

Mathias Fuchs is a game artist, musician, and media scholar. He pioneered in the artistic use of computer games and exhibited work at ISEA, SIGGRAPH, transmediale, and the Greenwich Millennium Dome. In 2012, he became a professor at Leuphana University in Lüneburg and is currently working at the Institute of Culture and Aesthetics of Media. Publications include *Phantasmal Spaces* (2019), *Diversity of Play* (2015), and “Weltentzug und Weltzerfall,” in *Philosophical Perspectives on Play* (2015). [mathias.fuchs@leuphana.de]

Tracy Fullerton is an experimental game designer, professor, and director emeritus of the USC Games program. Her research center, the Game Innovation Lab, has produced several influential independent games, including *Cloud* (2005), *fOw* (2006), *Darfur Is Dying* (2006), *The Night Journey* (2007) with artist Bill Viola, and *Walden, a Game* (2017), a simulation of Henry David Thoreau’s experiment at Walden Pond, which was named Game of the Year at Games for Change 2017 and Developer Choice at IndieCade 2017. Tracy is the author of *Game Design Workshop: A Play-centric Approach to Creating Innovative Games* (2004, 2008, 2014), a design textbook used at game programs worldwide, and holder of the Electronic Arts Endowed Chair in Interactive Entertainment. Prior to USC, she designed games for companies that include Microsoft, Sony, and MTV, among many others. Tracy’s work has received numerous honors, including an Emmy nomination for interactive television; Indiecade’s Sublime Experience, Impact, and Trailblazer awards; Games for Change’s Game Changer award; the Game Developers Choice’s Ambassador Award, and *Time Magazine*’s Best of the Web.

Anthony Y. H. Fung is a professor in the School of Journalism and Communication at the Chinese University of Hong Kong. He is also a professor in the School of Art and Communication at Beijing Normal University at Beijing, China. His research interests and teaching focus on popular culture and cultural studies, popular music, gender and youth identity, cultural industries and policy, and digital media studies. He has published widely in international journals and authored and edited more than twenty Chinese and English books. His recent books are *Youth Cultures in China* (2016; coauthored with Jeroen de Kloet), *Global Game Industries and Cultural Policy* (2016), and *Hong Kong Game Industry, Cultural Policy and East Asian Rivalry* (2018). [b763704@mailserv.cuhk.edu.hk]

Enrico Gandolfi, PhD, is an assistant professor of educational technology at Kent State University, Ohio. He previously worked as an associate researcher at Luiss “Guido Carli” University of Rome, Italy. His research interests span games and simulations for learning, augmented and virtual reality, accessibility and critical design in education, digital interfaces for special populations, and instructional streaming. He is the author of several journal articles (for *Journal of Gaming & Virtual Worlds*, *Convergence*, *Games and Culture*, *Simulation and Gaming*, *Well-Played*, *E-learning and Digital Media*, *Information Visualization*, *Feminist Media Studies*, and *International Journal of Information and Learning Technology*) and book chapters about these topics and the monographs *Piloti di Console* (2011), *Nerd Generation* (2014), and *Independent Videogames* (2015). He has been co-Principal Investigator and key personnel for

projects awarded by the GAR Foundation, the National Science Foundation, and the National Endowment for Humanities. [enrigand@gmail.com]

Manuel Garin is an associate professor in film and media studies at Universitat Pompeu Fabra, Barcelona, where he completed his PhD dissertation, which focused on visual humor and was later published as a book: *El gag visual. De Buster Keaton a Super Mario* (2014). He has been a visiting scholar at different institutions, such as the Tokyo University of the Arts, the University of Southern California, and Columbia University, where he developed the comparative media projects “Gameplaygag: Between Silent Film and New Media” and “A Hundred Busters,” which were financed by competitive public grants. His research on cinema, video games, and serial narratives has been published in scientific journals such as *International Journal of Cultural Studies*, *Communication & Society*, *Feminist Media Studies*, *L’Atalante*, *EPI*, and *Comparative Cinema* and in books. As a cultural critic, he has written for magazines such as *La Maleta de Portbou*, *Rockdelux*, *Contrapicado*, and *Cultura/s La Vanguardia*. Trained as a musician, he holds a professional degree in piano and an MFA in film scoring from ESMUC Music School. He is currently editing the digital humanities project “A Hundred Busters: Keaton across the Arts,” about the influence of Buster Keaton on different artists throughout the last century. [manuelgarin@gmail.com]

Ben Gill is a graduate of the University of California, Santa Barbara, with a degree in film and media studies and a minor in English literature. Currently living in San Francisco, he was born in Sheffield,

England and has since lived in various parts of England, Japan, and California. He has written about music, film, and video games for outlets that include *LA Music Blog* and *GameDynamo*. [benrgill@gmail.com]

Harrison Gish is a doctoral candidate in UCLA’s Cinema and Media Studies program. His work appears in the edited collection *How to Play Video Games* (2019) as well as the journals *eLudamos*, *Mediascape*, and *CineAction*. He is a member of the Society for Cinema and Media Studies Video Game Studies Scholarly Interest Group, of which he was the cochair from 2014 to 2017, and the Learning Games Initiative. [harrison.gish@gmail.com]

Anne Githuku-Shongwe is the representative for UN Women’s South Africa Multi-Country Office (SAMCO), which is responsible for women’s empowerment and gender equality in Botswana, Lesotho, Swaziland, and Namibia as well as South Africa, where the office is based. A key responsibility of her work is to develop women-owned businesses and the leadership capacity of women both in the public and private sectors. Anne is the founder of Afroes Games, a tech education social enterprise with multiple award-winning games. Prior to her new assignment at SAMCO, Anne spent eight years as a globally recognized and pioneering social entrepreneur, digital innovator, and thought leader on technology for development. Anne founded Afroes in 2010 to create innovative educational products to engage and equip African youth with life skills and connect them to future work opportunities. Afroes has received multiple awards, including the UN’s PeaceAPP; the MEFFYs Award,

London; and Netexplo Award, Paris, among others. Anne was recognized for the prestigious Schwab Social Entrepreneur of the Year 2013 Award. [anne.shongwe@gmail.com]

René Glas is an assistant professor of new media and digital culture in the Department of Media and Culture Studies at Utrecht University. With a background in film and new media studies, his primary field is game studies, in which he teaches and writes about a variety of topics, including game history and culture, cheating and other forms of deviant play, and games/play literacy. Glas is a founding member of Utrecht University's Center for the Study of Digital Games and Play. His book *Battlefields of Negotiation: Control, Agency, and Ownership in World of Warcraft* was published in 2012. In 2019, he coedited *The Playful Citizen: Civic Engagement in a Mediatized Culture*. [r.glas@uu.nl]

Tim Glaser studied literature, art, and media studies at the University of Konstanz and the Charles University in Prague. Since 2016, he has worked as a research assistant at the Institute for Media Studies at the Braunschweig University of Art, and he is a PhD candidate. His research interests include video game culture, comic studies, and speculative fiction. A recent publication is "Oh No—This Comic Is Literally Me. Webcomics im Zeitalter ihrer memetischen Rezeption" in *CLOSURE: Kieler e-Journal für Comicforschung*, issue 4.5, "Formen der Selbstreflexivität im Medium Comic," edited by Nina Heindl and Véronique Sina (2018). His website is www.timglaser.de. [t.glaser@hbk-bs.de]

Eitan Glinert is the founder of Fire Hose Games, the Boston-based game studio

behind *Slam Bolt Scrappers* and *Go Home Dinosaurs*. He did graduate research at the Massachusetts Institute of Technology on highly usable and accessible video game interfaces. He is especially impressed that you are reading this and cannot wait to play your game. [glinert@gmail.com]

Christopher Goetz is an assistant professor of cinematic arts at the University of Iowa. A film, digital media, and video game scholar, Chris's research focuses on fantasy and play across media. His published works have appeared in *Games and Culture*, *Game Studies: The International Journal of Computer Game Research*, *Camera Obscura*, *New Media & Society*, *The Psychoanalytic Study of the Child*, and an edited volume on queer game studies. His book project, *The Counterfeit Coin: Video-games and Fantasies of Empowerment*, is currently under review. He is one of the founding organizers of the Queerness and Games Conference. [christopher-goetz@uiowa.edu]

Martin "Retro Rogue" Goldberg is a Gen Xer who has been a video game fan since first walking into a bowling alley back in the 1970s and playing *PONG*. He received his nickname from his willingness to go to thrift stores and pawnshops in areas others will not go near, usually inspiring the comment, "Marty, I'm not about to get killed over an Atari cartridge!" Besides working in the video game industry as a programmer and technical writer, he is also a professional industry historian and member of the International Game Developers Association Preservation Special Interest Group. A regular contributor to the award-winning *Retro Gamer* magazine and the former site director of IGN/GameSpy's ClassicGaming.Com, Marty is currently working on several

books and archiving projects with noted Atari historian and archiver Curt Vendel. Marty is also the cofounder of the Midwest Gaming Classic, one of the largest fan-based video game shows in the United States. His quest for knowledge and passion for archiving has also resulted in the Electronic Entertainment Museum archives, a portion of which can be seen every year at the Midwest Gaming Classic. [wgungfu@gmail.com]

Racquel M. Gonzales is a doctoral student in the Department of Visual Studies at the University of California–Irvine. She obtained an MA in media studies from the Department of Radio-Television-Film at the University of Texas at Austin. Her research interests include historiography, genre theory, performance studies, and the intersections among gaming, histories of technology, and the spectacle. [racquelmgonzales@yahoo.com]

Sebastián González Canepa has been involved in the video game industry for over a decade at top Chilean development houses and is also an interactive media professor. For the past few years, he has worked as a producer at indie game development company ACE Team and previously at Wanako Games (acquired in 2008 by Behaviour Interactive). He currently teaches at Instituto Profesional Arcos, Santiago. He holds a BFA in interactive design and game development from the Savannah College of Art and Design. From 2008, he was an instructor for the Experimental Development Workshop at Universidad de las Américas until 2010, and in 2011, he became a professor and co-creator of the curriculum of the Videogame Development and Digital Animation track at Universidad del Pacífico, the first professional video game career program in Chile.

He is also the former vice president of the Videogames Chile Trade Association VGChile. He has worked on more than a dozen games for all major platforms, the most memorable being the *Rock of Ages* and *Zeno Clash* sagas. [hola@moresebastian.com]

Pawel Grabarczyk is a postdoctoral researcher at IT University of Copenhagen. He is an analytic philosopher who worked on philosophy of language (mostly theories of meaning) and philosophy of mind (mostly the problem of mental representations). His current work explores the boundaries between philosophy, computing, and game studies. His recent work involves game ontology, the study of independent games, and virtual reality. He is also interested in the history of computing and gaming platforms. [pawg@itu.dk]

Louis-Martin Guay is an assistant professor of game and interactive design at the University of Montréal, Canada. With a bachelor's degree in drama and a master's degree in film studies, he has been involved in game design for more than twenty years. His research focuses on learning in games, a systemic approach to game design, narrative and the aesthetic history of pinball machines, and the relation between video games and heavy metal music. [louis.martin.guay@uMontreal.ca]

Stephan Günzel is a professor of media science at the Technical University of Berlin. His research interests include first-person shooter games, phenomenology, concepts of space, media theory, and game studies. His publications include *Ludotopia: Spaces, Places and Territories in Computer Games*, edited with Espen Aarseth (2019). [stephan.guenzel@tu-berlin.de]

Ian Hamilton is a game accessibility specialist with a thirteen-year background in raising the bar for gamers with disabilities through advocacy, raising awareness (writing, speaking, organizing events, and community building), and consulting (working with studios from the smallest indies to the largest triple-A game makers, with publishers, platforms, industry, and government bodies). He is also codirector of GAconf and coordinator of <http://gameaccessibilityguidelines.com>. [i_h@hotmail.com]

Christopher Hanson is an associate professor in the English Department at Syracuse University, where he teaches courses in games studies, digital media, television, and film. His book *Game Time: Understanding Temporality in Video Games* was published in 2018, and his next book project is on game designer Roberta Williams. He previously worked for a number of years in video game and software development. [cphanson@syr.edu]

Todd Harper is an assistant professor in the Simulation and Game Design program at the University of Baltimore. His scholarly work ranges from work in esports and competitive fighting games, to queer and gender representation issues, to the ways that games construct body types, but he is also active in the critical community and industry as a writer and advocate. He tries to be angry in a constructive way via twitter at @drtoddharper. [tharper@ubalt.edu]

Philip Hausmeier received his diploma in communication design from the University of Applied Sciences Düsseldorf in 2003 and his MFA from the Slade School of Art London in 2005. Between 2005 and 2015, he worked as an artist internationally, with a focus on immersive spatial installations. In

2013, Hausmeier saw the potential of VR/AR/MR technologies for design and art and since then has exclusively worked with these media. In 2016, he founded the company Metaphysics as part of an accelerator in Silicon Valley to create structures that bring virtual reality and the arts together. Resulting exhibitions have been shown at the Computer History Museum in Mountain View, California; the Zabludowicz Collection in London; and the ZKM in Karlsruhe, Germany. In 2017 he cofounded the VR art database RadianceVR.co, which currently presents over one hundred international VR artworks and exhibits them in cooperation with museums and other partners. He is cofounder and UX designer of Meshicon Software, a mixed reality company that provides interface solutions for the Microsoft HoloLens. In addition, he organizes the Virtual Reality Berlin Meetup (VRBLN), one of the largest communities for VR with over thirty-three hundred members. He has been also lecturing on virtual reality and mixed reality at several universities in Berlin for the past five years. [mail@philiphausmeier.com]

Mark Hayse is a professor of Christian education at MidAmerica Nazarene University in Olathe, Kansas. His publications on video games include “Ultima IV: Simulating the Religious Quest” in *Halos and Avatars: Playing Video Games with God* (2010), entries in *The Concise Dictionary of Pop Culture and Theology* (forthcoming), and a chapter in *The Legend of Zelda and Theology* (forthcoming). His research interests include curriculum theory, theology, and ludology. [mahayse@mnu.edu]

Leonard Herman, or “The Game Scholar,” fell in love with video games the first time he played *PONG* at a local bowling alley in 1972. A programmer and technical writer

by trade, Herman founded Rolenta Press in 1994 to publish his book *Phoenix: The Fall & Rise of Videogames*, the first serious book on video game history, which, in 2008, *Game Informer* magazine called the second-best book about video games ever written. The current fourth edition of the book, now called *Phoenix IV: The History of the Videogame Industry*, is the most comprehensive video game history book ever written. Herman has written articles about video games for *Electronic Gaming Monthly*, *Edge*, *Games*, *Videogaming Illustrated*, the *Official US PlayStation Magazine*, and many other magazines. He also wrote chapters for books such as *Supercade* (2001) and *The Video Game Explosion* (2007) and edited Ralph Baer's book *Video-games: In the Beginning* (2005). He also wrote game manuals for eight Atari VCS and two Magnavox Odyssey² games. In 2003, Herman was given a Classic Gaming Expo Achievement Award. An adviser to the National Videogame Museum, Herman resides in New Jersey with his wife, Tamar. [lenny@rolentapress.com]

Alejandro Iparraguirre is a higher technician in marketing and an electronics technician, is a producer, designer, and cultural manager promoting the video game industry. He is a full professor of the Bachelor of Electronic Arts at the National University of Tres de Febrero and professor of playful culture of the Bachelor of Design at the University of San Andrés. He currently stands out in the video game development industry as a founding member of FundAV (Fundación Argentina de Videojuegos), and he is coordinator of the video game area for the Ministry of Culture of the Argentine Nation. His specific work is as a playful designer and producer in the coordination of the development team and as a consultant

for production, human resources, marketing, and communication in the video game sector. Outstanding creation and participation projects include Game Work Jam (a video game development promotion event) and *Element Space* (a science fiction video game). [aleiparraguirre@gmail.com]

Joshua Jarrett is a lecturer specializing in esports at Staffordshire University. After completing his PhD in 2019, Josh's research focused on a playfully co-creative approach to understanding the political economy of multiplayer online battle arena games. Josh's ongoing research interests include affective understandings of in-game micro-transactions, ethnographic research into grassroots esports cultures, and critical political economic analysis of esports global development. [joshua2jarrett@live.uwe.ac.uk]

David Javet is one of the cofounders of the UNIL Gamelab at the University of Lausanne. He is a board member of the Swiss Game Developers Association (SGDA) as well as the coordinator of monthly game developers' gathering in the French-speaking part of Switzerland. In parallel with his research activities, he works as a curator for the Numerik Games Festival in Yverdon-les-Bains. David is also a narrative designer and producer at Tchagata Games, a game design creative hub based in Lausanne. [david.javet@unil.ch]

Jennifer Jenson is an associate professor of pedagogy and technology in the Faculty of Education at York University. She has published on gender and gameplay, gender and technology, and the design and development of digital games for education. She and a team of students recently completed a health-based game, *Epidemic: Self-Care for Crisis*, and she is coeditor of *Loading: The*

Journal of the Canadian Game Studies Association. [jjenson@edu.yorku.ca]

Ashley P. Jones is a PhD student in Georgia State University's Moving Image Studies program with an emphasis in feminist media studies and digital game studies. She is currently working on research exploring the feminist and queer aesthetics and mechanics within digital gaming. She has written on the nostalgic effects of Lara Croft in the *Tomb Raider* game series as well as the hauntological aspects of the game *Tacoma*. [ajones306@student.gsu.edu]

Rhys Jones is a PhD candidate studying fan cultures and games at the Hong Kong Polytechnic University. He has published papers on room escape games, sociopolitical representations of Hong Kong in video games, and transgressive gameplay practices. [rhys.gj@hotmail.co.uk]

Kristine Jørgensen is a full professor in media studies at the University of Bergen, Norway. Her research interests include the relationship between games and players, game aesthetics, and the Norwegian game industry. She is the author of *A Comprehensive Study of Sound in Computer Games* (2009) and *Gameworld Interfaces* (2013) and is the main editor of *Transgression in Games and Play* (2019). Her book *The Paradox of Transgression in Games* (with Torill Elvira Mortensen) was published in 2020. [Kristine.Jorgensen@uib.no]

Jesper Juul is an associate professor at the Royal Danish Academy of Fine Arts, School of Design, and has developed several master's-level programs in game design at the ITU of Copenhagen, at the New York University Game Center, and at KADK in Copenhagen. He has published four books:

Half-Real (2005), *A Casual Revolution* (2009), *The Art of Failure* (2013), and *Handmade Pixels* (2019). He is also a coeditor of the Playful Thinking Series. [j@jesperjuul.net]

Radwan (RAD) Kasmiya is a pioneering game creator and serial entrepreneur in the Middle East and China, having created the first video game and computer-generated animation there and many best sellers, such as *Under Ash* (2001), the first first-person shooter video game in the Middle East; *Quraish* (2005), a real-time strategy game; *Under Siege* (2004); *Road to Jerusalem* (2009); *Knights of Glory* (2012); and *Swords of Glory* (2018). Kasmiya was awarded the Creative Young Entrepreneur Award in Syria in 2007 as founder of AfkarMedia, cofounded Falafel Games Ltd (2011) and WafaGames (2017) in China, and has worked on many gaming projects with Disney-Pixar, THQ, Ubisoft, EA, and others on titles such as *BattleField 2* (2005), *Assassin's Creed* (2007), *World in Conflict* (2007), *Far Cry 2* (2008), *Tom Clancy's EndWar* (2008), *WALL•E* (2008), *Red Faction: Guerilla* (2009), and *Up* (2009). Kasmiya holds an electronic/computer engineering degree from the University of Damascus and is passionate about interactivity and AI evolution in video games. [kasmiya@gmail.com]

Dafna Ester Kaufman is a first year PhD student in communication at UNC–Chapel Hill. She completed her MA in the School of Film, Media and Theatre at Georgia State University. She also received a certificate in Women and Gender Studies (at Georgia State). Her general research interests are sports media, affect theory, gender theory, critical race theory, and cultural studies. [dkaufman1@student.gsu.edu]

Andrew Kemp-Wilcox is a doctoral candidate in the School of Film, Media, and Theatre at Georgia State University in Atlanta. Andrew's background as a game designer, narrative designer, and producer in the social and mobile game space has influenced his doctoral research toward the textual elements of digital games, including narrative, aesthetics, mechanics, and ludic opposition. [wkemp2@student.gsu.edu]

Brendan Keogh is an Australian Research Council DECRA Fellow in the Digital Media Research Centre, Queensland University of Technology. He is the author of *A Play of Bodies: How We Perceive Video-games* (2018) and *Killing Is Harmless: A Critical Reading of Spec Ops: The Line* (2012) and has written extensively about the cultures and development practices of video games for outlets such as Overland, the Conversation, Polygon, Edge, and Vice. [brendan.keogh86@gmail.com]

Aphra Kerr has a PhD in communication studies (2000) and is an associate professor in the Department of Sociology at Maynooth University, Ireland. She has been researching digital games for almost twenty years and founded the community website www.gamedevelopers.ie. She is co-principal investigator on the "Refiguring Innovation in Digital Games" project and a collaborator of the ADAPT SFI Centre for Digital Content Technology. In 2016, she received a Distinguished Scholar award from the international Digital Games Research Association (DiGRA). She currently serves as an expert adviser to the Pan European Games Information (PEGI) system and is a member of the Media Literacy Ireland network. She has held visiting fellowships at the University of Edinburgh (2019) and the University of Pennsylvania

(2011). Aphra's books include *Global Games: Production, Circulation and Policy in the Networked Age* (2017), and she co-edited *The International Encyclopedia of Digital Communication and Society* (2015). See more at <https://www.maynoothuniversity.ie/people/aphra-kerr>. [aphra.kerr@mu.ie]

Wesley Kirinya was born in 1983 in Nairobi, the capital city of Kenya. I have lived most of my life in Nairobi. I went to Conso-lata High School and graduated in 2001. I got my first job right after high school. I taught computers to children between the ages of nine and eleven. It was a very interesting challenge. I would say that I learned a lot of patience and understanding from the children. My heart was more in software development than teaching. I had a lot of free time on my hands, so I began developing software part-time. I had a good background in software development from high school. My first commercial software was a school management system integrated to a school's website. My second software was the Kenya Catholic Directory, a directory that maintains contact information of activities and institutions of the Catholic community in Kenya. I then joined the University of Nairobi for Computer Science. However, I had done a lot of work in computers before I joined the university and therefore changed my focus to actuarial science because I was interested in mathematics. I had set my mind on making games as a career by the time I joined university, but I still needed to know more about game development. I bought books and manuals from the United States. After my second year of university, I deferred my studies to develop *Adventures of Nyangi* (2007), the first game I developed. Because of the game, I won an award as Africa's Top ICT Youth Innovator in 2008 and made valuable

contacts in the professional game development industry. I needed more experience in professional software development and joined Genkey Africa, located in Ghana, as a senior software developer. After one year, I cofounded Leti Games in Ghana. I am married with no children. [wesley@leti games.com]

Carly A. Kocurek is a doctoral candidate in American Studies at the University of Texas at Austin. Her current research focuses on the relationship between early video gaming, the production of masculinity, and the social and economic upheaval of the 1970s and 1980s. She holds an MA in American studies from the University of Texas. She is coauthor of *Republic of Barbecue: Stories beyond the Brisket* and a former senior editor of *Flow*, an online journal of television and media studies. At present, she is completing a series of oral history interviews related to early video game culture. [womanofkleenex@gmail.com]

Kyle Kontour has an MA in film and media studies from the University of Otago and a PhD in communication from the University of Colorado–Boulder. His research is broadly concerned with game studies and new media, with a particular emphasis on the military entertainment complex and its impact on, and relationship to, cultural production, gender, performance, discipline, and the conduct of war. His previous work has appeared in the journals *Refractory* and *Digital Culture and Education*. [kkontour@gmail.com]

Lars Konzack is an associate professor in information studies at the Department of Communication (COMM) at the University of Copenhagen (UCPH). Konzack has an MA in information science and a PhD in

multimedia from Aarhus University. He is also cofounder of the game developing academy DADIU. His fields of studies are ludology, geek culture, and imaginary worlds, and his publications include “Computer Game Criticism: A Method for Computer Game Analysis,” “The Cultural History of LEGO,” “Mark Rein•Hagen’s Foundational Influence on 21st Century Vampiric Media,” and “Viking Re-Enactment.” [lars@konzack.dk]

Tanya Krzywinska is author of a range of papers and books that seek to distinguish the formal and aesthetic characteristics of games. She has also written extensively on the Gothic and horror in relation to game form. Tanya was an early member of DIGRA, acting as president in 2006 until 2010. Since 2014, she has been editor in chief of the peer-reviewed journal *Games and Culture*. Tanya has convened a range of games courses that provide students with the experience, knowledge, and skills needed for employment in the games industry. Tanya holds the chair in digital economy at Falmouth University, Cornwall, United Kingdom, and is director of the Games Academy that provides incubation-based and innovation-led game development and game art courses (www.falmouth.ac.uk/games). Given time, Tanya continues to practice as an artist. [tanya.krzywinska@falmouth.ac.uk]

Julian Raul Kücklich is an independent new media researcher. He has been conducting research on the aesthetics, politics, and semiotics of digital games since 2001 and has published a number of papers on these topics in journals such as *Convergence*, *Game Studies*, and *Games & Culture*. He is also the author of *Playability* (2008). [julian@kuecklich.de]

Laura Iseut Lafrance St-Martin is a lecturer in communication and a PhD student in semiology at the University of Quebec in Montreal (UQAM), for which she was awarded a scholarship from the Quebec Research Fund–Society and Culture (FRQSC). Her thesis focuses on J. R. R. Tolkien’s semiotic theory. She is a research assistant for the research chair on big data and gaming communities and an active member of the Homo Ludens research group and the Research Group on Everyday Information and Surveillance (GRISQ). She has written journal articles and book chapters about video games, gaming communities, and the semiotic analysis of big data. [iseut.lafrance@gmail.com]

Nicolle Lamerichs is a senior lecturer and team lead in creative business at HU University of Applied Sciences, Utrecht. She holds a PhD in Media Studies from Maastricht University (2014). In her book *Productive Fandom* (2018), she explores intermediality, affect, costuming, and creativity in fan cultures. Her research focuses on participatory culture and new media, specifically the nexus between popular culture, storytelling, and play. [n.a.lamerichs@gmail.com]

Michael Liebe is CEO and founder of Booster Space, the company behind Gamesweekberlin, the QUO VADIS conference, Gamefest, VR NOW Con & Awards, Womenize!, and many other events driving to connect the business, technology, and culture of games, VR, and other media. The company also developed and published the game *DUEL VR* (2017). Michael is an advocate of crowdfunding and supports Kickstarter as Games Outreach in Europe since January 2016. In the times before Booster Space, he co-initiated the indie games and art festival, A MAZE., the Digital Games

Research Centre of the University of Potsdam (DIGAREC), and the Computer Games Collection of European Media Studies at the University of Potsdam, the European Master’s program, Ludic Interfaces, and the Games:net Berlinbrandenburg. Until 2012, he was the adviser of new media at the Medienboard Berlin-Brandenburg and was responsible for marketing and networking for the “new media” industry in the German capital region. He holds an MA in European media studies and is an adviser and jury member and works as university lecturer at UE Germany. [michael.jw.liebe@googlemail.com]

Henry Lowood is Harold C. Hohbach Curator, History of Science & Technology Collections and Film & Media Collections, at Stanford University. He is a lecturer in the Science, Technology, and Society Program and the Film and Media Studies Program at Stanford. Since 2000, he has led the How They Got Game Project in the Stanford Humanities Laboratory (SHL) and the Stanford Libraries, a research project focused on the history of computer games and simulations; between 2004 and 2008, he also served as codirector of the SHL. Among the many initiatives undertaken by the How They Got Game Project are the Machinima Archive and the Archiving Virtual Worlds collection, for which he is curator, hosted by the Internet Archive. He also led Stanford’s work on the Preserving Virtual Worlds project and the Game Citation project. He has published widely on the history of science and technology, library and archival studies, and digital game studies. For more information, visit <https://lowood.people.stanford.edu/curriculum-vitae>. [lowood@stanford.edu]

Martin Lütke is currently an assistant professor at the John F. Kennedy Institute for

North American Studies at Freie Universität Berlin. Lütke published the monographs *"We Missed a Lot of Church, So the Music Is Our Confessional": Rap and Religion* (2008) and *Color-Line and Crossing-Over: Motown and Performances of Blackness in 1960s American Culture* (2011). He is working on *Habilitation Wire Writings: Media Change in the Culture of the Progressive Era*. He keeps buying the new PES every year and tells himself that it is somehow better than the one before. [martin.luethe@fu-berlin.de]

Vincent Mauger is a PhD student in the Design and Digital Culture Ad Hoc Doctoral Program at Université Laval, Québec City, where he is part-time lecturer and research professional in UX design. He also taught at Université de Montréal and Université du Québec en Abitibi-Témiscamingue. Most of his courses focus on interactive storytelling, video game design, and screenwriting. His research interests include narrative design, transmedia storytelling, video game characters, and fictional worlds as well as design epistemology. He contributed to the Homo Ludens Research Group and NT2 Lab at the Université du Québec à Montréal and currently works at the Urban Science Joint Research Unit (UMRsu) in partnership with Co-DOT, a cognitive ergonomics research laboratory at Université Laval. [vincent.mauger@design.ulaval.ca]

Frans Mäyrä is a professor of interactive media, game studies, and digital culture at the University of Tampere in Finland. He has studied the relationship of culture and technology since the early 1990s. He specializes in the cultural analysis of technology, particularly on the ambiguous, conflicting, and heterogeneous elements in this relationship, and has published on topics that include information technologies,

science fiction and fantasy, the demonic tradition, the concept of identity, and role-playing games. He is currently teaching, researching, and heading numerous research projects in the study and development of games, new media, and digital culture. He has also served as the founding president of the Digital Games Research Association (DiGRA). His publications include *Koneihminen* (editor; Man-Machine, 1997), *Demonic Texts and Textual Demons* (1999), *Johdatus digitaaliseen kulttuuriin* (editor; Introduction to Digital Culture, 1999), *CGDC Conference Proceedings* (editor, 2002), *Lapsuus mediamaailmassa* (editor; Childhood in the World of Media, 2005), *The Metamorphosis of Home* (editor, 2005), and *An Introduction to Game Studies* (2008). [frans.mayra@uti.fi]

Ken S. McAllister is a professor of rhetoric and the College of Humanities associate dean of Research and Program Innovation at the University of Arizona. [mesmer@email.arizona.edu]

Greg McLemore is a lifelong enthusiast of coin-operated and amusement technology, history, and culture. Among Greg's other responsibilities, he serves as the executive director of the Museum of the Game (including the International Arcade Museum, the Killer List of Videogames, Penny Arcadia, and the Vintage Arcade Preservation Society). He also serves as a director of the nonprofit International Arcade Museum Library. In recent years, Greg has assembled a leading collection of amusement and arcade art, history, memorabilia, and machines, including the first three floor model coin-operated arcade machines made by man (each the only specimen surviving), the first coin-operated kiddie ride, and numerous coin-op and console video game prototypes and rarities.

Greg grew up playing an Atari 2600 and text adventure and arcade games on an Apple IIe. In 1983, he launched one of the first online electronic bulletin board systems, primarily serving video game enthusiasts. The service quickly added one of the first text adventure games playable online that was available to anyone in the world with a modem and, just a few years later, one of the online role-playing adventure games featuring simultaneous multiperson play. Today, his favorite machines to play are penny arcade machines made before 1930 and golden age coin-operated video games made between 1978 and 1983. Besides his involvement with arcade history preservation, he is a successful serial entrepreneur, having started dozens of businesses in the technology, real estate, and media industries. Greg lives with his family in Los Angeles, California. [mclemore@webmagic.com]

Kyle Moody is an assistant professor in communications media at Fitchburg State University. His research is broadly focused on social media and online communities, with a focus on how convergent media users are involved in the production and dissemination of user-generated content. He has published multiple works on the intersection of games and users, including “*Ico* and *Shadow of the Colossus*: The Importance of Companion Characters in Lonely Landscapes” (2017) and “The End of the Dream: How *Grand Theft Auto V* Simulates and Subverts Its Male Player-Character Dynamics” (2017). He is currently working on a book broadly focused on fake news and culture. [kmoody4@fitchburgstate.edu]

Sebastian Möring is an assistant professor in European media studies, a joint study program of the University of Potsdam and the University of Applied Sciences

Potsdam, Germany, and head coordinator of the DIGAREC (Digital Games Research Center of the University of Potsdam). His research focuses on the philosophy and aesthetics of computer games, in-game photography, and representations and functions of climate in computer games. Sebastian earned his PhD from the Center for Computer Games Research at the IT University of Copenhagen with a thesis on the metaphor discourse in game studies. He researched existential structures of computer games as a postdoc at the School of Creative Media, City University of Hong Kong. Sebastian is involved with the Gamephilosophy Network and an organizer of the annual Philosophy of Computer Games conference. For publications and more information, please visit <http://sebastianmoering.com>. [smoering@uni-potsdam.de]

Souvik Mukherjee is currently employed as an assistant professor of English literature at Presidency University (previously Presidency College), Calcutta. Souvik has been researching video games as an emerging storytelling medium since 2002 and completed his PhD on the subject at Nottingham Trent University in 2009. He has done postdoctoral research with the Humanities faculty of De Montfort University, United Kingdom, and as a research associate at the Indian Institute of Technology in New Delhi, India, where he worked on digital media as well as narrative analysis. His research examines their relationship to canonical ideas of narrative and also how these games inform and challenge current conceptions of technicity, identity, and culture, in general. His current interests involve the representations of empire in video games; the analysis of paratexts of video games, such as walkthroughs and

after-action reports; and the concept of time and telos in video games. His research has been published in *Journal of Gaming and Virtual Worlds* and *Writing Technologies* as well as in various edited collections on game studies and popular culture. His other interests are digital humanities and early modern and classical literature. Souvik regularly writes about his research on his blog *Ludus ex Machina* (<http://readinggamesandplayingbooks.blogspot.com/>) and welcomes comments and feedback. As a gamer, he prefers strategy games, although he is a big fan of *Fallout 3* and the *STALKER* games. [prosperosmaze@gmail.com]

Sheila C. Murphy is an assistant professor in the Department of Screen Arts & Cultures at the University of Michigan. Her work and teaching are centered around new media theory, video games, internet media, and cultural reception. She is the author of *How Television Invented New Media* (2011). She believes that video games are crucial to understanding contemporary media culture and to the study of new media because video game systems truly were the first “PCs.” Her next project explores how geek culture emerged alongside cute culture online—from sprites to Strong Bad and beyond. [scmurphy@umich.edu]

Gathoni Mwai is a sustainable development professional who has spent the last eight years working on social development issues in Africa and focusing on the use of data, technology, and innovation for development. Having been brought up in Kenya, she is passionate about the country, its people, and in making an impact to improve the livelihoods of the most vulnerable in society. Gathoni holds a bachelor’s degree in social science (anthropology, geography, and international relations) from Durham

University. She joined Afroes as a project manager for the development of *Haki II: Chaguo Ni Lako* (*Justice: The Choice Is Yours*; 2013), the PeaceApp award-winning mobile game that was used for peace building in Kenya in the run up to the 2013 elections following the postelection violence experienced in August 2007. Having completed her master’s in sustainable development corporate responsibility, Gathoni returned to Afroes, where she has taken on the role of Kenya programme manager, and she is tasked with scaling the Afroes Games catalogue, developing multistakeholder partnerships, and managing several pan-African projects. [gathoni@afroes.com]

Andrei Nae, PhD, is an assistant lecturer at the University of Bucharest, where he teaches American literature and English language courses. In 2017, he defended his doctoral thesis, entitled *Immersion and Narrativity in the Survival Horror Genre*, and has published multiple articles and chapters on topics such as video game cultural studies and the relationship between video games and literature. He is currently working on a research monograph, *Immersion, Narrative, and Gender Crisis*, which elaborates on the argument of his dissertation. [andrei.nae@lils.uni-buc.ro]

Víctor Navarro-Remesal is a researcher in game studies and a specialist in East Asian studies. As an assistant professor at CESAG (Comillas Pontifical University), in Palma (Spain), he teaches video games, interactive narrative, and animated cinema. His research interests are player freedom; Zen Modes and Zen-inspired games; Japanese games, or *gêmu*; and game preservation. He has published many papers and book chapters on those matters and is the author of *Libertad dirigida: Una gramática del*

análisis y diseño de videojuegos (2016) and *Cine Ludens: 50 diálogos entre el cine y el juego* (2019) and is a coauthor of *Game& Play: Diseño y análisis del juego, el jugador y el sistema lúdico* (2015). [vnavarro@gmail.com]

David Nelson serves as director of adjudication services for Twin Galaxies International and is also considered one of the top arcade game players, holding multiple world records, particularly on the older “monochrome” titles. He grew up in Laconia, New Hampshire, and has always been a video game enthusiast, ever since his days of playing Atari 2600 nearly every day after elementary school. His fascination with video games was nurtured by growing up in the same town as what is now the largest video game arcade in the world, Funspot. His ability as a player was unparalleled in his community, although no one knew it. This was of course during a time when video gaming was considered to be a waste of time and was only pursued by geeks and nerds and people with no life; it was, however, the one thing he truly excelled at. He had always wished there was some way he could put his skills to use and be recognized for his talents in gaming.

It was not until 1999 that he discovered Twin Galaxies, when it came to his hometown to cohost the first International Classic Video Game Tournament. It was here that he met many gaming legends as well as industry icons such as Walter Day. Following this event, he joined the New Hampshire Pro Video Game Team, soon helping to cocaptain and later head up the team himself, which he renamed the NH Video Warriors (which sounded much cooler!). He quickly immersed himself in the sport of competitive video gaming, and in 2000, he joined the staff of Twin Galaxies as a

referee. Over the next decade, he continued his passion for gaming and competition by participating in many tournaments and hosting contests of his own; he soon became a top competitor. He dedicated a lot of his efforts to helping other players become recognized champions with Twin Galaxies and eventually moved up the ranks to become chief of the referee team in 2008. Today, he strives to inspire video game players all over the world to play their best and leave their mark in the sport of competitive video gaming, a job that he feels he has always been destined to do.

Benjamin Wai-ming Ng is currently a professor of Japanese studies at the Chinese University of Hong Kong, where he teaches and researches Japanese popular culture and Japan–Hong Kong relations. He received his doctorate in East Asian studies from Princeton University in 1996 and was an assistant professor in Japanese studies at the National University of Singapore from 1996 to 2001. He is working on a research project on the interaction and collaboration between Japan and Hong Kong in the ACG (anime-come-game) industry. [waimingng@cuhk.edu.hk]

Benjamin Nicoll is a lecturer in media and communication and a member of the Digital Media Research Centre in the School of Communication at Queensland University of Technology. He is the author of *Minor Platforms in Videogame History* (2019) and coauthor, with Brendan Keogh, of *The Unity Game Engine and the Circuits of Cultural Software* (2019). [b2.nicoll@qut.edu.au]

Michael Nitsche is an associate professor at the Georgia Institute of Technology in Atlanta, where he leads the interdisciplinary Digital World and Image Group, which

focuses on the interconnections between digital and physical spaces. He is the author of *Video Game Spaces* (2009), and he is coeditor with Henry Lowood of *The Machinima Reader* (2011). His current work focuses on digital media as a means of self-expression and human performance. [michael.nitsche@lcc.gatech.edu]

Rolf F. Nohr is a professor of media aesthetics and media culture at Braunschweig University of Arts and an external affiliate at the College of Humanities, University of Arizona. His recent publications are *Unternehmensplanspiele 1955–1975. Die Herstellung unternehmerischer Rationalität im Spiel* (2019) and *The Cake Is a Lie! Polyperspektivische Betrachtungen des Computerspiels am Beispiel von Portal*, edited with Thomas Hensel and Britta Neitzel (2015). [fitzenohr@gmx.de]

David O’Grady is a doctoral candidate in the Cinema and Media Studies program at UCLA. His most recent publications include a chapter on Nintendo’s D-pad controller in the anthology *How to Play Video Games* (2019), a chapter on cutscenes and time in video games in *The Game Culture Reader* (2013), and an essay on Wes Anderson’s *The Life Aquatic with Steve Zissou* (2004) for the journal *New Review of Film and Television Studies* (March 2012). David is currently a researcher and coordinator in the UCLA Game Lab, a board member of *[in] Transition: Journal of Videographic Film & Moving Image Studies*, and an instructor at California State University, Long Beach. His dissertation examines video game interactivity and the implications of interface design and use on the experience of play. [david@davidogrady.com]

Minako O’Hagan is an associate professor in the School of Cultures, Languages, and

Linguistics at the University of Auckland. Specialized in applied translation studies, she has been involved in technology-oriented research from interdisciplinary perspectives. For the last decade, her main research interest has been game localization and nonprofessional translation. Her coauthored publication *Game Localization* (O’Hagan and Mangiron, 2013) is the first major monograph on the topic in translation studies. [minako.ohagan@auckland.ac.nz]

Maria Luján Oulton is a cultural producer and curator specialized in experimental art video games. She has a degree in public and institutional relations and a master’s degree in communication and cultural creation by the Walter Benjamin Foundation (thesis awaiting jury). She is cofounder of the Latin American Meeting of Videogames, GAIA (Game Arts International Assembly) and cofounder of the cultural producer Objeto a, focused on art and technology. She is dedicated to the divulgation of experimental and artistic video games, fostering their insertion in the cultural field and encouraging female participation in the industry. She has given talks and participated in events such as TEDx Riodelaplata (Buenos Aires), Jorge Tadeo Lozano University (Bogotá), DevHourmx (Mexico City), and DiGRA (Melbourne, Australia), among others. [lujan.oulton@objeto-a.com.ar]

Caren Pagel is a doctoral candidate in moving images studies at Georgia State University. Her research interests include video game cultures, conflicts between industry and players over agency and ownership, and the relationship between player game labor and the rise of player-led controversies. [cpagel1@gsu.edu]

William Clyde Partin III is a doctoral candidate in communication at the

University of North Carolina. His research examines the impact of platformization on cultural industries, especially video games, livestreaming, and esports. He is also a research affiliate at UNC's Center for Information, Technology, and Public Life, where he examines knowledge-making practices in far-right conspiracy communities. He publishes in journals such as *Surveillance & Society* and *Social Media + Society* and writes about culture and technology for popular outlets such as *The Atlantic*, *Vice*, and *Jacobin*. [wcpartin@live.unc.edu]

Matthieu Pellet is a lecturer at the University of Lausanne and is finishing his PhD on the heroic figure in Mediterranean antiquity. Of course, he was also bathed in video games since his childhood and continues to spend a lot of time with them. He was an organizer and speaker at the first Swiss international academic conference, Powers of Video Games: From Practices to Discourses, and also held a class called Video Games and Virtual Worlds at the Swiss Federal Institute of Technology Lausanne (EPFL). Matthieu is also graphic designer and cofounder of Tchagata Games, a creative hub dedicated to the exploration of gaming, in whatever form or support. [matthieu.pellet@unil.ch]

John Reid Perkins-Buzo is interested in the areas where technologies of the past and present meet the arts of the moving image (animation, cinema, and gaming). He has advanced degrees in both the fine arts and applied mathematics/computer science. He continues to develop software for moving image projects, including for a variety of wearable devices. He is an assistant professor of digital media in the Radio-TV-Digital Media Department at Southern Illinois University, Carbondale. [reidop@mac.com]

Bernard Perron is a full professor of film and games studies at the University of Montreal. He has coedited *The Video Game Theory Reader* (2003), *The Video Game Theory Reader 2* (2008), *The Routledge Companion to Video Games Studies* (2014), *Figures de Violence* (2012), *The Archives: Post-Cinema and Video Game between Memory and the Image of the Present* (2014), *Z pour Zombies* (2015), and *Video Games and the Mind: Essays on Cognition, Affect and Emotion* (2016). He has edited *Horror Video Games: Essays on the Fusion of Fear and Play* (2009). He has also written *Silent Hill: The Terror Engine* (2012) for the Landmark Video Games book series he is coediting, and *The World of Scary Video Games: A Study in Videoludic Horror* (2018). His research and writings concentrate on video games, interactive cinema, the horror genre, and narration, cognition, and the ludic dimension of narrative cinema. More information can be found at his research team website: <http://www.ludov.ca/>. [bernard.perron@umontreal.ca]

Martin Picard is a visiting lecturer and research associate at the Department of East Asian Studies in Leipzig University. His teaching and research interests cover Japanese video games and cinema as well as video game history and aesthetics. He has published articles in journals such as *Game Studies* and chapters in anthologies such as *The Routledge Companion to Video Game Studies* (2014), *The Video Game Theory Reader 2* (2008), *Horror Video Games: Essays on the Fusion of Fear and Play* (2009), and *The Video Game Explosion: A History from PONG to PlayStation and Beyond* (Greenwood Press, 2007). [martin.picard@videotron.ca]

Rachel F. Pickett is an associate professor of psychology at Concordia University

Wisconsin. Her research interests include topics in college student development, vocational psychology, and multicultural issues. Some of her recent publications include an article in the *Journal of Trauma & Dissociation* titled “Nonpathologizing Trauma Interventions in Abnormal Psychology Courses” and several pieces on undergraduate vocational discernment found on vocationmatters.org. [rachel.pickett@cuw.edu]

Teddy Pozo is a PhD student in film and media studies at the University of California–Santa Barbara. Her research interests include video games, digital video, and the politics of gender in digital culture. [teddy_pozo@brown.edu]

Daniel Reynolds is an associate professor in the Department of Film and Media Studies at Emory University. His is the author of *Media in Mind* (2019) and articles in *Game Studies*, *Film Quarterly*, and *Fibreculture*. [daniel.reynolds@emory.edu]

William B. A. Robinson is completing a master’s degree in video game studies at Concordia University in Montreal, Canada. He has written about the aesthetics of play and is currently researching player imagination, user-generated content, and the cultures of motion control at Concordia’s Center for Technoculture, Art, and Games. [wbarobinson@gmail.com]

Guillaume Roux-Girard is an invited professor within the Creation and New Media unit at University of Québec in Abitibi-Témiscamingue (Montréal campus). His current research focuses on the act of listening to video games. [guillaume.roux-girard@uqat.ca]

Judd Ethan Ruggill is a professor and head of the Department of Public and Applied Humanities at the University of Arizona.

He is an inveterate (albeit accidental) media archivist. [jruggill@email.arizona.edu]

TreaAndrea M. Russworm is an associate professor of English at the University of Massachusetts, Amherst, and a series editor of *Power Play: Games, Politics, Culture* (2008). She is the author of *Blackness Is Burning: Civil Rights, Popular Culture, and the Problem of Recognition* (2016) and a coeditor of *Gaming Representation: Race, Gender, and Sexuality in Video Games* (2017) and *From Madea to Media Mogul: Theorizing Tyler Perry* (2016). Additionally, her work has been published in *The Velvet Light Trap*, *Frontiers*, and *Black Camera*. She is currently writing a fourth book on race, video games, and the politics of play. [russworm@english.umass.edu]

Taiyoung Ryu is a game designer and game researcher. He has worked on more than fifteen titles across a broad range of platforms, including PC, online, console, and mobile platforms in the United States and Korea. After he earned an MFA at the University of Southern California’s Interactive Media Division in 2010, he started a game studio in Korea. Since 2009, he has served as the Asia regional chair for IndieCade. He has also conducted research on microtransaction models and the brain-computer interface. His articles have been published in a number of journals. He has also had a chance to give talks on the subjects at conferences, including GDC and DiGRA. As a journalist for the game industry, he writes articles for newspapers and journals. [taiyoungryu@gmail.com]

Ulf Sandqvist has a PhD in economic history from Umeå University. His main research area relates to the development of computer culture and the game industry, particularly in Sweden and the Nordic region. [ulf.sandqvist@umu.se]

Rita Santoyo Venegas holds a PhD in philosophy from the National Autonomous University of Mexico (UNAM). She wrote a doctoral dissertation in which she analyzes how knowledge is created through the experience of digital play by interacting with digital games. She also explores the foundations of an epistemology that incorporates digital play as experiential knowledge. Her main research interests are ethics, epistemology, philosophy of technology, and game studies. She is a member of the Institute for Design Research (IF) at the University of Applied Sciences Europe. She has presented papers on philosophy and video games in the International Congress of Philosophy in Mexico, Philosophy at Play at the University of Gloucestershire, the Future and Reality of Gaming Conference in Vienna, and Game-Camp in Berlin. Her recent publications include “Digital Games and the Collaborative Construction of Knowledge in Paidia” (2017; <http://www.paidia.de/digital-games-and-the-collaborative-construction-of-knowledge/>) and “Digital Play as Epistemological Experience” in *Philosophies of Play as Praxis*, a forthcoming collection of papers from the Philosophy at Play conference. [lunazapdos@gmail.com]

Damien B. Schlarb works as an assistant professor (nontenure) of English at Johannes Gutenberg University, Mainz, Germany, where he teaches courses on American literature and culture. He earned his PhD in English from Georgia State University (USA). His research focuses on digital game studies as well as nineteenth-century American literature and culture. He has served as assistant and managing editor, respectively, for the peer-reviewed academic journals *South Atlantic Review* (South Atlantic Modern Language Association) and *Amerikastudien/American Studies*

(German Association for American Studies). He is currently preparing to publish a book on Herman Melville and the Old Testament. His new project examines the various forms of work in video games. His work on video games appeared in the edited collection *Playing the Field: Video Games and American Studies* (2019). [dbschlarb@gmail.com]

Stefan Schubert is an assistant professor at the Institute for American Studies at Leipzig University, Germany. In 2018, he received his PhD for a project investigating what he calls “narrative instability” in films, video games, and TV, a study that was published in 2019 as *Narrative Instability: Destabilizing Identities, Realities, and Textualities in Contemporary American Popular Culture*. His wider research interests include popular and visual culture, narrativity, textuality, new media, game studies, gender studies, and post-postmodernism. He has published on questions of narrative and agency in video games such as the *BioShock* series, *Heavy Rain* (2010), and *The Stanley Parable* (2013), and he is a member of the DFG research network “Narrative Liminality and/in the Formation of American Modernities.” [stefan.schubert@uni-leipzig.de]

Kevin Schut is a professor of media and communication, a game development program lead, and an associate dean of the School of the Arts, Media + Culture at Trinity Western University in Langley, British Columbia, Canada. He received his PhD in communication studies at the University of Iowa in 2004. His current research focuses on moral and ethical choice in video games. He is the author of the book *Of Games and God* (2013), and he has published articles and chapters on *No Man's Sky* (2016) as an imaginary world, LEGO video games,

fantasy role-playing games and masculinity, mythology in computer games, Evangelicals and games, and the presentation of history in strategy games. [kevin.schut@twu.ca]

Bobby Schweizer is an assistant professor in the Department of Journalism and Creative Media Industries in the College of Media & Communication at Texas Tech University. He researches the history of theme parks, expressive narrative environments, and game design and play. Bobby is the coauthor of *Newsgames: Journalism at Play* (2010) and coeditor of *Meet Me at the Fair: A World's Fair Reader* (2014). [schweizer@gatech.edu]

Jean Paul Simon is founder of JPS Public Policy Consulting, a consulting firm that specialized in media and telecom law regulation and strategy. He has held various positions in the telecom industry and worked as a senior scientist at the Institute for Prospective Technological Studies (IPTS), European Commission, Directorate-General JRC. He holds a PhD in philosophy (1975) and is a graduate (MBA) from the Ecole des Hautes Etudes Commerciales (HEC; MBA in, econometrics, 1971). He has written several books and articles on communications and public policy. He is a frequent speaker on telecommunications and media in Asia, Europe, and the United States. [jpsmultimedia@hotmail.com]

Tim Skelly is the author of the classic Cinematronics vector-based arcade games *Star Hawk* (1978), *Sundance* (1978), *Warrior* (1979), *Rip-Off* (1980), *Star Castle* (1980), and *Armor Attack* (1981). His non-vector games for D. Gottlieb/Mylstar include *Reactor* (1982), *Insector* (1983), and *Screw Loose* (1984). Today, these games are highly prized by collectors. He is an artist and

illustrator of several books and magazine articles and is the author of *Shoot the Robot, Then Shoot Mom* (1983), a book of cartoons about classic arcade games. In 1985, as part of a small group of friends and fellow game veterans, he cofounded Incredible Technologies. While there, he was responsible for the visual aspects of all products. He devised and created the primary screen displays for Virtual Worlds' original *BattleTech Center* (1990) and for that project designed the Mad Cat and other Clan OmniMechs. During his time at Incredible Technologies, he took an interest in human-computer interface issues and, drawing on his video game experiences, became active in the HCI community.

After a stint as art director with the SEGA Technical Institute, where he contributed to *Sonic the Hedgehog 2* (1992), he was recruited to be one of the first researchers in the Microsoft User Interface Research Group. While at Microsoft, he often lectured on campus and at conferences on the topic of "seductive interfaces," his research into how user interfaces affect the user. Partially because of that work, he was appointed to the 1996 Panel on Human-Computer Interface Technologies by the U.S. government. He helped found Microsoft's Lifelike Computer Character Conference and has contributed to conferences held by the AAAI, ACM SIGGRAPH, and ACM SIGCHI, presenting tutorials on interface design. He has been a member of the advisory board and a contributor to the *Handbook of Interface Design* (1997), and for a number of years, he was a member of the editorial advisory board for Morgan Kaufmann's series of user interface-related books.

Songsri Soranastaporn, PhD, is an associate professor in English teaching, researcher,

and course developer. She teaches English, research methodology, material development, and leadership for information and communication technology and is an expert in English for Specific Purposes. Songsri is the coordinating editor of the “Association News & Notes” column of *Simulation & Gaming Journal* and the cofounder (2008) and the secretary general of the Thai Simulation and Gaming Association (ThaiSim), which invites scholars around the world to join its international conference every year. In addition, she is on the committee of the e-Learning Association of Thailand (e-LAT), which aims to strengthen, promote, and establish e-learning quality and standards (www.e-lat.or.th). She is an editor and reviewer of both Thai and international journals and conferences, such as *Current Topics in Management*, the *Kasetsart Journal* (social sciences) at Kasetsart University, the *Journal of Language and Culture* at Mahidol University, Khonkan University’s *International Journal of Humanities and Social Science*, *RMUSTV Research Journal*, *International Conference on Advances in Management* (ICAM), ThaiSim International Conference, and the International Conference on Computers in Education (ICCE). [songsrisoranastaporn@hotmail.com]

Doug Stark is a PhD student in the English Department at the University of North Carolina, Chapel Hill. Doug’s dissertation focuses on the military, industrial, and artistic implementation of play and games in the postwar to midcentury United States. He explores how the archive on cybernetic discourse, behavioral management, and aleatory aesthetics not only reveals an enduring epistemological ground for the computer game, gamification, and experimental new media art as we know them

today but also a resource for playful futures not yet taken by the march of history. Otherwise, his research and teaching concern twentieth- and twenty-first-century literature, film, and new media, always with an eye to questions of action, embodiment, mediation, and constructions of the human. He has publications on Afrofuturism, video game literature, and walking simulators in *Extrapolation* (2020), *Playing the Field: Video Games and American Studies* (2019), and the *Journal of Gaming & Virtual Worlds* (2020), respectively. [doge@live.unc.edu]

Jaroslav Švelch is assistant professor of media studies at Charles University, Prague. He has published work on history and theory of computer games, on humor in games and social media, and on playful forms of political participation and activism. His monograph *Gaming the Iron Curtain: How Teenagers and Amateurs in Communist Czechoslovakia Claimed the Medium of Computer Games* (2018) traces the hidden histories of home computing and gaming in the former Soviet bloc. In 2007–08, he was a visiting researcher at MIT’s Comparative Media Studies department, and in 2017–19, he was a postdoctoral fellow at the University of Bergen, Norway, working on a project about the history, theory, and reception of monsters in games. He is a cofounder of the Central and Eastern European Game Studies conference. [jšvelch@gmail.com]

Grant Tavinor is a lecturer in philosophy at Lincoln University, New Zealand. He is author of *The Art of Videogames* (2009) and a number of scholarly articles on video games, art, and ethics. [grant.tavinor@lincoln.ac.nz]

Carl Therrien is a professor in games and film studies at Université de Montréal and a

member of the LUDOV research group (www.ludov.ca). He has cofounded the History of Games international conference series (www.history-of-games.com). Therrien has published several papers and book chapters on immersion and on video game historiography, for instance, “Grasping the ‘French Touch’: A Data-Assisted Cultural History of the Adventure Genre” (*Games and Culture*, 2019), “Now You’re Playing with Adverts: A Repertoire of Frames for the Historical Study of Marketing Discourse” (*Kinephanos*, 2017), and “Inspecting Video Game Historiography through Critical Lens: Etymology of the First-Person Shooter Genre” (*Game Studies*, 2015). His first book, *The Media Snatcher* (2019), prolongs this work in the context of the Platform Studies series; NEC’s PC Engine/TurboGrafx-16 and its CD-ROM extension provides an ideal case study to illustrate methodological issues about the way video game history is constructed and the complex remediation operating between games, cinema, and anime. [carl.therrien@gmail.com]

Michael Thomasson is one of the most widely respected video game historians in the field today. He currently teaches college-level video game history, design, and graphics courses, and in 2014, *The Guinness Book of World Records* declared that Thomasson had “The Largest Video Game Collection” in the world. For television, Michael conducted research for MTV’s video game–related program *Video MODS*. In print, Michael authored *Down-right Bizarre Games: Videogames That Crossed the Line* (2016) and has contributed to nearly a dozen texts, including the publication by the inventor of home video games, *Videogames: In the Beginning* (2005) by Ralph H. Baer; *Bill Kunkel’s Confessions of*

the Game Doctor (2005); both volumes of the *Encyclopedia of Video Games* (2012), and more. His historical columns have been distributed worldwide in newspapers and magazines. Michael has written business plans for several video game vendors and managed almost a dozen game-related retail stores spanning three decades. He has also contributed toward or published dozens of games for several consoles, such as the SEGA CD, ColecoVision, 3DO, Intellivision, Vectrex, CD-i, and several Atari platforms. Michael’s classic gaming business also sponsors retrogaming tradeshow and expos across the United States and Canada. Mr. Thomasson resides in New York with his wife, JoAnn, and daughter, Anna. His website is www.GoodDealGames.com. [service@gooddealgames.com]

Staci Tucker was a master’s student and teaching fellow of communication and society in the School of Journalism and Communication at the University of Oregon in Eugene. Her research encompassed a range of topics surrounding the intersection of media technologies, identity, and community, including online games. Her projects included an examination of harassment and discrimination based on gender, race, and sexual orientation in massively multiplayer online games as well as an analysis of how data storage structures and online forms impact categories of identity. She has served in various positions as an online manager, programmer, designer, server, and database administrator since 1998. These positions included technology consulting roles in newspapers, media, and education. [stucker@uoregon.edu]

Çetin Tüker is an animator, illustrator, instructor, and architect specializing in 3-D animation, interactive multimedia, and

motion graphic design. He completed his undergraduate and graduate education at the METU Department of Architecture in 1992 (BA) and 1996 (MA) and completed his thesis for his doctor of fine arts (DFA) at Mimar Sinan Fine Arts University, Department of Graphic Design, in 2009. Since 1993, he has received several awards for his animations and designs in several fields. He continues his teaching career, which started in 1994, as an associate professor in the Mimar Sinan Fine Arts University, Department of Graphic Design. In 2007, he published his first book, *From Design to Application: 3D Environment Design*, and in 2007 and 2008, his educational DVDs, *Introduction to 3DS Max* (2007) and *Fluid Simulation with GLU 3D* (2008), were released by the Gnomon Workshop. [cetin_tuker@yahoo.com]

Ethan Tussey received his PhD from the University of California–Santa Barbara in 2012. He is an associate professor of film and media at Georgia State University. His work explores the relationship between the entertainment industry and the digitally empowered public. His book, *The Procrastination Economy: The Big Business of Downtime* (2018), details the economic and social value of mobile device use in the context of the workplace, the commute, the waiting room, and the living room. He has contributed book chapters on ESPN's *Pardon the Interruption*, DC's *SuperHero Girls* action dolls, creative labor, online sports viewing, connected viewing, sports and social media, and crowdfunding to various anthologies. He is also the graduate director of the School of Film, Media & Theatre as well as the coordinating editor of *In Media Res* and the cofounder of the Atlanta Media Project. He teaches classes on media industries, media theory and history, and digital media. [ethantussey@gmail.com]

John Vanderhoef is an assistant professor of film, television, and media in the Communications Department at California State University, Dominguez Hills. His research interests include indie media, digital labor, and media industries. His book *Passion, Pixels, and Profit: The New Creative Economy of Indie Game Production* explores the influence of romantic individualism and neoliberal ideology on the creative economy of indie game production. He has published works in journals such as *Television and New Media* and *Ada* and in edited collections such as *Production Studies the Sequel!: Cultural Studies of Global Media Industries* (2015). He is also an avid narrative game maker and has exhibited digital games at festivals such as Slamdance DIG, WordPlay, and PixelPop Festival. [jvanderhoef@csudh.edu]

Curt Vendel has extensive experience on a professional level in corporate America working as an IT consult for numerous financial banking firms as well as internet infrastructure management. On a personal level, Vendel's interests and experience in the video game industry is multifaceted as a game player, historian, and video game software designer and hardware engineer. Vendel was involved in an advisory role in the infrastructure layout and design of fun.com's *Anarchy On-Line* (2001), a multiuser immersive role-playing game environment. His thorough understanding of the video game industry and knowledge of the current pros and cons involved in the popular MMORPG *EverQuest* (1999) were beneficial in the deployment of this new next-generation gaming environment.

Vendel's true personal passion and devotion lies in the Atari Museum, a network of former Atari employees who have worked together for the preservation of

the vast documentation, schematics, technical designs, hardware, and software of the once great video game industry pioneering company. Over the past twenty years, an immense archive has been formed to preserve and present materials that would have surely become refuse in local dumps if not for his devotion and intervention. Vendel has written articles for several video gaming publications; acted extensively as a research reference and source for many books, articles, and software titles; and appeared on several television programs. He also has electronics design knowledge and resurrected a once-thought-lost Atari product called the 7800 High Score Cartridge. Working with a former Atari employee who supplied him with some technical documents and source listing, Vendel was able to recreate this product and market and privately sell it to the classic gaming community.

After many years running his three computer consulting firms, Vendel has retooled his consulting firms toward the video gaming industry and is now involved in the design and creation of numerous hardware and software products for many of the industry's larger and more well-known firms, including Fossil, Logitech, and Atari. He even designed a *Guitar Hero* (2005) game controller for Gene Simmons of Kiss, based on the original AXE guitar. [curt@atarimuseum.com]

Jasper van Vught is an assistant professor in the Department of Media and Culture Studies at Utrecht University. His research focuses on game theory and methodology, game ethics, and game history. He is part of the Centre for the Study of Digital Games and Play, has worked within a large international research project into the classification

of games and the dominant experience of violence in entertainment games, and is involved in a project by the Netherlands Institute for Sound and Vision dedicated to the preservation and canonization of Dutch game history. [J.F.vanVught@uu.nl]

Rachel Wagner is an assistant professor of religious studies at Ithaca College. Her work centers on the complex relationship between religion and culture, especially the intersection of technology with religious belief and practice. She has just published a full-length study titled *Godwired: Religion, Ritual, and Virtual Reality* (2011). [rwagner@ithaca.edu]

Matthew Weise is a game designer whose work spans industry and academia. He is the CEO of Empathy Box, a company that specializes in narrative design for games and across media. He was the narrative designer at Harmonix Music Systems on *Fantasia: Music Evolved* (2014), the game design director of the GAMBIT Game Lab at MIT, and a consultant for Warner Bros., Microsoft, Eko, PBS, the National Ballet of Spain, and others on storytelling and game design. His work, both creatively and critically, focuses on transmedia adaptation with an emphasis on the challenges of adapting cinema into video games. Matt has given lectures and workshops on film-to-game adaptation all over the world and has published work on how franchises such as *Alien*, *James Bond*, and horror cinema in general are adapted into games. Links to his writing and game design work, including his IGF-nominated *The Snowfield* (2011), can be found at www.matthewweise.com. [matthew.weise@gmail.com]

Karin Wenz is an assistant professor of digital cultures at Maastricht University in the Netherlands at the Faculty of Arts and Social

Sciences. Her interests include digital cultures, especially the interrelation between games and art, machinima, and theorycrafting. She also has investigated hacking and death and death rituals in digital games. Her publications include articles on digital literature, game communities, game art, theorycrafting, hacking, and digital death. [k.wenz@maastrichtuniversity.nl]

Thomas Westin is lecturing in game development at the Department of Computer and Systems Sciences, Stockholm University, Sweden. His current research concern is how to support the game industry in making digital games more accessible and inclusive. Thomas teaches design science approaches for user-experience evaluation of games as well as inclusive design approaches of games. He has also worked with game development and received the Innovation in Audio Award for his first 3-D game at the Independent Games Festival, USA, in 2003. He started the IGDA Game Accessibility SIG in 2003 and has run several game accessibility roundtables at the Game Developers Conference since 2004. He was guest professor at CNAM, Paris, in 2018, where he also assisted to set up the first European Game Accessibility Conference, #GAConfEU. [thomasw@dsv.su.se]

Zach Whalen is an assistant professor in the Department of English, Linguistics, and Communication at the University of Mary Washington, Fredericksburg, Virginia. His continuing research and teaching focuses on new media, with a specific focus on video games, typography, textual theory, and comics. With Laurie N. Taylor, he coedited *Playing the Past: History and Nostalgia in Videogames* (2008). His articles have appeared in *Refractory*, *Game Studies*, *Work and Days*, and *Flow*. He has also

contributed chapters to *Music, Sound and Multimedia* (2007) and *The Meaning and Culture of Grand Theft Auto* (2006). His current project, *The Videogame Text*, adapts his 2008 dissertation on typography and textuality in video games into something book shaped. [zach.whalen@gmail.com]

Colin Wheeler is a doctoral candidate in film, media, and theater at Georgia State University. His current areas of scholarship include video games, qualitative data analysis, media industries, and cultural studies. His dissertation focuses on ethnographic methodologies applied to below-the-line labor in Atlanta's creative industries. Graduating from the Savannah College of Art and Design—Atlanta in 2014 with an MFA in animation, Colin practices critical media scholarship while also freelancing in media production. He also works as senior programmer for ASIFA-South, selecting international independent shorts for film festivals. In the future, he hopes to teach theory and design classes that skirt the line between the practical and theoretical. [cwheeler11@student.gsu.edu]

Markus Wiemker studied sociology, philosophy, and psychology with the focus on media and cultural studies at the University of Technology RWTH Aachen in Germany. He has been teaching game design and game studies at various schools and universities in Germany, Austria, and Singapore and also developed game design curricula for institutions in Europe, Southeast Asia, and West Africa. Besides his research interests in the regulation and censorship of digital games, he works as a storyteller and game designer in the areas of toys, games, and gambling. Currently, he is professor of game design at the Media Akademie-Hochschule Stuttgart (mAHS), University

of Applied Sciences, Germany. [markus@weimkar.org]

Hanna E. Wirman is an associate professor in games and play design at the IT University of Copenhagen. Her research focuses on marginal and critical ways of playing and making games, including game fandom, serious games, diversity, regional play cultures, and the design and research of animal play. Recently, she has published about play in Hong Kong covering game arcades, escape rooms, Mahjong, game jams, games news, games in special education, and locally developed serious games. [hanna.wirman@gmail.com]

Bryan-Mitchell Young is a PhD candidate in Indiana University's Department of Communication and Culture, where he is completing his dissertation on local area network parties. His research uses ethnographic methods to examine issues surrounding computer-mediated communication, boundaries between "real" and "virtual," and performances of race and gender. His work combines qualitative research methods with media studies to examine how our identities are shaped by our interactions with technologies and how those technologies are used in ways in which the designers of those technologies did not anticipate. He has maintained a blog at popularculture

gaming.com since 2002. [byoung86@ivytech.edu]

Nelson Zagalo is an associate professor at the University of Aveiro-Portugal. He founded the scientific laboratory EngageLab and the Portuguese Society for Videogames Sciences and is now the coordinator of the research group Games and Transmedia at Digimedia/UA. He has more than one hundred peer-reviewed publications in the fields of narrative, games, and creativity. He founded and cochairs the *Journal of Digital Media & Interaction* and has published the books *Interactive Emotions, from Film to Videogames* (2009), *Videogames in Portugal: History, Technology and Art* (2013), and *Creativity in the Digital Age* (2015). [nzagalo@ua.pt]

Xenia Zeiler is a tenure-track professor of South Asian studies at the University of Helsinki, Finland. Her research is situated at the intersection of digital media and culture in India and the worldwide Indian community, with a focus on video game development. She is the author of numerous academic articles and book chapters on mediatized Indian culture and society, including the first ever article on video games and Hinduism. She is cofounder and coeditor in chief of the academic journal *Gamevironments*. [xenia.zeiler@helsinki.fi]
